Multiple gamma mechanisms co-exist in an excitatory/inhibitory network

Gamma oscillations have been implicated in many cognitive functions. Fast spiking interneurons are thought to play an important role in gamma synchrony. Recently, fast spiking interneurons in the entorhinal cortex have been shown to exhibit type 2 excitability and postinhibitory rebound (PIR). Theoretical work has shown that these properties make interneuronal network gamma (ING) more robust than in networks of type 1 interneurons. Here we show that this robust ING persists in a sparsely connected excitatory network. We also show that phase response curve (PRC) theory can predict under what circumstances the interneurons will sparsely synchronize in two clusters, and how increasing the delay and/or the conductance destabilizes two clusters in favor of a single cluster.

CONVEX COCOMPACT SUBGROUPS IN REAL PROJECTIVE GEOMETRY I: Introduction to convex real projective structures and divisible convex sets. Two definitions of convex cocompact subgroup in real projective space

This series of lectures is about a theory of convex cocompactness for discrete subgroups of the projective general linear group acting on real projective space. These groups display geometric and dynamical behavior similar to convex cocompact groups in rank one Lie groups (hyperbolic geometry) with some interesting differences. Some of this lecture series is based on joint work with Francois Gueritaud.
Complex Analysis, Dynamics and Geometry
Monday, April 09, 2018, 4:00pm-5:00pm
3096 East Hall
Takahiro Shibata (Kyoto University)
Ample canonical heights for endomorphisms on projective varieties

Given a smooth projective variety on a number field and an endomorphism on it, we would like to know how the height of a point grows by iteration of the action of the endomorphism. When the endomorphism is polarized, Call and Silverman construct the canonical height, which is an important tool for the calculation of growth of heights. In this talk, we will give a generalization of the Call-Silverman canonical heights for not necessarily polarized endomorphisms, ample canonical heights, and propose an analogue of the Northcott finiteness theorem as a conjecture. We will see that the conjecture holds when the variety is an abelian variety or a surface.

Student Combinatorics Seminar
Monday, April 09, 2018, 4:00pm-5:00pm
3866 East Hall
Combinatorics Grad Students (University of Michigan)
Bring Your Work to Work Day!

Unipotent Representations of Real Groups

In 1980 Jim Arthur conjectured the existence of certain unipotent representations of reductive groups over local fields, which should play a fundamental role in the study of automorphic forms. Arthur did not give a definition of these representations (only some properties), and they are still not well understood, even in the case of Archimedean fields. I will discuss progress on the case of the real field. An aspect of this is the Atlas of Lie Groups and Representations, which is a software project to, among other things, understand unipotent representations and the unitary dual of real reductive groups.

The boson-fermion correspondence

The boson-fermion correspondence is an isomorphism between the symmetric and exterior algebras of a vector space of countably infinite dimension. The name comes from the fact that bosons are particles which can share the same state (like the factors in an element of the symmetric algebra), whereas fermions must occupy distinct states (like the factors in an element of the exterior algebra). The isomorphism is interesting because it is compatible with the actions of various Lie algebras (the Heisenberg Lie algebra, gl_infty, affine sl_n) on each space. The correspondence is closely related to the combinatorics of partitions and Schur functions, and it has been used to prove combinatorial and probabilistic results.

This talk will be an introduction to the algebraic objects mentioned above, with an emphasis on their combinatorial interpretations. As an application, we will see how the boson-fermion correspondence immediately implies the Murnaghan--Nakayama formula for characters of the symmetric group.
This series of lectures is about a theory of convex cocompactness for discrete subgroups of the projective general linear group acting on real projective space. These groups display geometric and dynamical behavior similar to convex cocompact groups in rank one Lie groups (hyperbolic geometry) with some interesting differences. Some of this lecture series is based on joint work with Francois Gueritaud.

Can we make objects invisible? This has been a subject of human fascination for millennia in Greek mythology, movies, science fiction, etc. including the legend of Perseus versus Medusa and the more recent Star Trek and Harry Potter. In the last decade or so there have been several scientific proposals to achieve invisibility. We will introduce some of these in a non-technical fashion concentrating on the so-called “transformation optics” that has received the most attention in the scientific literature.

Recent empirical studies show that volatility could be rough, and thus it is natural to use Fractional Brownian Motion (fBM) to model the volatility. We are interested in the derivative pricing and hedging theory in such a model. However, fBM is neither a Markov process nor a semimartingale, then many standard methods relying on PDEs and/or martingales fail in this setting. By introducing the so called forward volatility as extra state variables, we “recover” the standard theory in this setting by using path dependent PDEs. Our main tool is a new functional Ito formula, in the spirit of Dupire.

This is a joint work with Frederi Viens.
We will consider the inverse problem of determining the sound speed or index of refraction of a medium by measuring the travel times of waves going through the medium. This problem arises in global seismology in an attempt to determine the inner structure of the Earth by measuring travel times of earthquakes. It has also several applications in optics and medical imaging among others.

The problem can be recast as a geometric problem: Can one determine the Riemannian metric of a Riemannian manifold with boundary by measuring the distance function between boundary points? This is the boundary rigidity problem. We will also consider the problem of determining the metric from the scattering relation, the so-called lens rigidity problem. The linearization of these problems involve the integration of a tensor along geodesics, similar to the X-ray transform.

We will also describe some recent results, join with Plamen Stefanov and Andras Vasy, on the partial data case, where you are making measurements on a subset of the boundary. No previous knowledge of Riemannian geometry will be assumed.

Given a compact complex curve, Simpson correspondence asserts that there exists a canonical diffeomorphism between the moduli space of representations of the fundamental group of the curve and the moduli space of Higgs bundles over the curve. The P=W conjecture predicts that via this (non-algebraic) diffeomorphism, the mixed Hodge structure and the perverse filtration correspond. In this talk, I will discuss how the multiplicativity of perverse filtrations and curious hard Lefschetz are related to the P=W conjecture. As concrete examples, I will introduce five families of Hitchin systems which are Hilbert schemes of points on surfaces. I will discuss why the perverse filtrations associated with these five families of Hitchin maps are multiplicative. The same method works for Hilbert schemes of points of elliptic K3 surfaces.

B735 East Hall
Jason McCullough (Iowa State University)

**Graded Shifts and the Shapes of Free Resolutions**

Let I be a homogeneous ideal in a polynomial ring $S = K[x_1, \ldots, x_n]$ over a field K. Many of the properties of the homogeneous ideal associated to I can be determined from the minimal graded free resolution of I. In my talk I will discuss some progress on understanding the maximal graded shifts (i.e. degrees of syzygy modules) of ideals and modules over S. I will present some new restrictions on the maximal graded shifts of ideals, which can be thought of as restrictions on the shapes of the nonzero entries in the graded Betti table of an ideal.

On weakly universal functions

A function $U: [\omega_1]^2 \rightarrow 2$ is called universal if for every function $F: [\omega_1]^2 \rightarrow \omega$ there is an injective function $h: \omega_1 \rightarrow \omega_1$ such that $F(\alpha, \beta) = U(h(\alpha), h(\beta))$ for each $\alpha, \beta \in \omega_1$. It is easy to see that universal functions exist assuming the Continuum Hypothesis, furthermore, by results of Shelah and Mekler, the existence of such functions is consistent with the continuum being arbitrarily large. Universal functions were recently studied by Shelah and Steprans, where they showed that the existence of universal graphs is consistent with several values of the dominating and unbounded numbers. They also considered several variations of universal functions, in particular, the following notion was studied: A function $U: [\omega_1]^2 \rightarrow \omega$ is $(1, \omega_1)$-weakly universal if for every $F: [\omega_1]^2 \rightarrow \omega$ there is an injective function $h: \omega_1 \rightarrow \omega_1$ and a function $e: \omega \rightarrow \omega$ such that $F(\alpha, \beta) = eU(h(\alpha), h(\beta))$ for every $\alpha, \beta \in \omega_1$. Shelah and Steprans asked if $(1, \omega_1)$-weakly universal functions exist in ZFC. We will study the existence of $(1, \omega_1)$-weakly universal functions in Sacks models and provide an answer to their problem.

Preprint Algebraic Geometry Seminar

Ziwet Lecture 3: Seeing Through Space and Time

We consider inverse problems for the Einstein equation with a time-depending metric on a 4-dimensional globally hyperbolic Lorentzian manifold. We formulate the concept of active measurements for relativistic models. We do this by coupling Einstein equations with equations for scalar fields.

The inverse problem we study is the question of whether the observations of the solutions of the coupled system in an open subset of the space-time with the sources supported in this set determines the properties of the metric in a larger domain. To study this problem we define the concept of light observation sets and show that knowledge of these sets determine the conformal class of the metric. This corresponds to passive observations from a distant area of space which is filled by light sources.

We will start by considering inverse problems for scalar non-linear hyperbolic equations to explain our method. No previous knowledge of Lorentzian geometry or general relativity will be assumed. This is joint work with P. Hinz, Y. Kurylev, M. Lasss and Y. Wang.

**Symplectic Reading Group**
Friday, April 13, 2018, 10:00am-11:00am
1360 East Hall
Dan Burns (UM)
Quantum speed limit vs. classical displacement energy (after L. Charles and L. Polterovich)

Here is the abstract for the paper:
"We discuss a link between symplectic displacement energy, a fundamental notion of symplectic topology, and the quantum speed limit, a universal constraint on the speed of quantum-mechanical processes. The link is provided by the quantum-classical correspondence formalized within the framework of the Berezin-Toeplitz quantization."

More specifically, the authors improve the "quantum speed limit" using Hofer displacement energy. The underlying question is the relation between quantum independence of a future state of a system and the analogous Hamiltonian displacement properties of such states in the classical (non-quantum) framework. The topics are based on themes previously discussed in the SRG, especially Alejandro Uribe's discussion of geometric quantization. The talk will only set the context of the discussion and indicate results and directions, i.e., there will not be time for detailed exposition of the techniques.

1360 East Hall
Montek Gill (University of Michigan)
Higher algebra and the Goodwillie calculus

The first part of this talk will describe higher algebra, which refers to algebraic structures which are analogous to the usual ones except that conditions such as associativity and commutativity are required only up to higher and coherent homotopies. For example, spectra are the higher analogue of abelian groups. I will describe the construction of higher structures first via topological operads and then via infinity-operads. The second part of the talk will describe the Goodwillie calculus, a calculus for homotopical functors. Again, I will first describe a topological approach, and then an infinity-categorical approach. I will use this calculus to give one possible precise formulation of how the passage from spaces to spectra is a linearization.

Kevin Hannay (Schreiner University)
Macroscopic models for coupled biological oscillators

We consider large systems of coupled limit cycle oscillators and develop a new approach for the systematic extraction of low-dimensional "macroscopic models" describing the dynamics of these systems. We identify an elegant structure in the phase distribution of experimental and simulated coupled biological oscillators. Further, we characterize the emergence of this structure using a simple argument based only on the general phase-locking behavior of coupled oscillators. We demonstrate how this structure may be applied as an ansatz to derive low-dimensional macroscopic models and apply it to derive a low-dimensional model for human circadian rhythms. Finally, we fit the human model to experimental data and compare the predictions to a predominant phenomenological model for human circadian rhythms.

Topographically induced Non-Gaussian Water Waves  

Rogue waves have been of great interest in recent times with several proposed generation mechanisms currently under investigation. We present new laboratory experiments that reveal that bathymetry can qualitatively alter the distribution of randomized surface waves; a normally-distributed incoming wave field becomes skewed and highly non-Gaussian after encountering a step in terrain. A short distance downstream of the step, the wave-field is very accurately characterized by the gamma distribution, affording simple estimates for the skewness, kurtosis, and other statistical properties. Importantly, the exponential decay of the gamma distribution is much slower than Gaussian decay, signifying that extreme events occur more frequently. Our results also show that popular measures of rogue activity may be misleading. Clean linear regressions in surface probability distribution parameters as a function of forcing amplitude allow for more quantitative work in the future.
There is a niche body of work on limiting shapes, i.e., asymptotic Newton polyhedra, of symbolic generic initial systems considered for polynomial rings in characteristic zero (e.g., by my academic sister Sarah Mayes-Tang, and separately by Dumnicki, Szemberg, Szpond, and Tutaj-Gasinska, a quartet of Polish mathematicians). In particular, in one joint paper the latter four authors compute the limiting shape for ideals defining zero-dimensional star configurations in projective space--star configurations turn out to be a steady source of a lot of interesting "ALGECOM" phenomenology. In this talk, we discuss work-in-progress to generalize their computation to the case of ideals defining zero-dimensional configurations in projective space determined by hypersurfaces of a common fixed degree. Along the way, we draw connections to a 2015 investigation (published in Transactions of the AMS in 2017) of select homological and asymptotic properties of hypersurface and matroidal configurations by Geramita, Harbourne, Migliore, and Nagel. I'll aim to close the talk by indicating how we might see--or "hear"--select asymptotic numerical invariants in the limiting shape: Waldschmidt constants, asymptotic Castelnuovo-Mumford regularity, and resurgences for homogeneous polynomial ideals.
