Deep Learning Methods for Stochastic Control And Partial Differential Equations

The numerical resolution of high-dimensional partial differential equations (PDEs) and stochastic control is a challenging problem in applied mathematics. Over the last five years, several deep neural networks-based algorithms have been proposed and have show their great efficiency for tackling these issues. In this talk, we give an introduction to this field of research, review the main results in this literature, and present some new developments, notably regarding mean-field control problems and Master equation in Wasserstein space.

Asymptotics of spherical integrals and large deviations of the largest eigenvalues for random matrices.

The Harish-Chandra-Itzykson-Zuber integral, also called spherical integral is defined as the expectation of $\exp(\text{Tr}(AUBU^*))$ for $A$ and $B$ two self adjoint matrices and $U$ Haar-distributed on the unitary/orthogonal/symplectic group. It was initially introduced by Harish-Chandra to study Lie groups. Since then, it has known many kinds of applications, from physics to statistical learning. In this talk we will study the asymptotics of these integrals when one of the matrices remains of finite rank. We will also see how to derive from these asymptotics large deviation principles for the largest eigenvalues for random matrix models that satisfy a sub-Gaussian bound.

*Colourful Convex Structure*

Given any 7 points in the plane, can you colour them red, blue, and yellow so that there is a point in the convex hull of each colour? While many combinatorial geometry problems are extremely difficult, this one can be answered completely. We will introduce and prove Tverbergs theorem, including an algorithm to find such a colouring. Along the way, we will see both Cautheodory’s theorem (about how simplices cover convex hulls) and a colourful generalization.

Fano varieties are complex algebraic varieties admitting positive Ricci curvature metrics. They form one of the three fundamental building blocks of algebraic varieties, thus their classification problem is important. However, it is known that moduli spaces of all Fano varieties have pathological behaviors. In this talk, I will explain that if we impose K-stability on Fano varieties, an algebraic condition arising from the study of Kähler-Einstein metrics, then we indeed get a compact moduli space. Based on joint works with H. Blum, D. Halpern-Leistner, C. Xu, and Z. Zhuang.

Space-time metric and Einstein’s equations lie at the foundation of general relativity. Somewhat surprisingly, one can start with an SU(2)-gauge theory, write down the simplest equations one can, without making reference to any background field, and show that the Riemannian geometry and Einstein’s equations emerge by setting up an appropriate dictionary. Equations of the ‘fundamental’ gauge theory are simple low order polynomials. Complexity of Einstein’s equations can be traced back to the fact that the explicit dictionary from the gauge theory to general relativity is rather intricate. The gauge theory framework provides new insights into general relativity, including an interesting interplay between the Lie algebra of volume-preserving diffeomorphisms and the ‘integrable’ sector of (anti-)self-dual solutions to Einstein’s equations. It also leads to a new infinite dimensional Lie algebra that generalizes the Lie algebra of the diffeomorphism group, opening up directions for new mathematical work. I will make a special effort to make the summary of these structures and results accessible to mathematicians as well as physicists.

Event will take place in-person and online via Zoom:

Second Van Eenam Lecture: Mean-Field Markov Decision Processes With Common Noise And Open-Loop Controls

We develop an exhaustive study of Markov decision process (MDP) under mean field interaction both on states and actions in the presence of common noise, and when optimization is performed over open-loop controls on infinite horizon. Such model, called CMKV-MDP for conditional McKean-Vlasov MDP, arises and is obtained here rigorously with a rate of convergence as the asymptotic problem of N-cooperative agents controlled by a social planner/influencer that observes the environment noises but not necessarily the individual states of the agents. We highlight the crucial role of relaxed controls and randomization hypothesis for this class of models with respect to classical MDP theory. We prove the correspondence between CMKV-MDP and a general lifted MDP on the space of probability measures, and establish the dynamic programming Bellman fixed point equation satisfied by the value function, as well as the existence of epsilon-optimal randomized feedback controls. The arguments of proof involve an original measurable optimal coupling for the Wasserstein distance. This provides a procedure for learning strategies in a large population of interacting collaborative agents.

K-stability and moduli of quartic K3 surfaces

We show that K-moduli spaces of (P^3, cS) where S is a quartic surface interpolates between the GIT moduli space and the Baily-Borel compactification as c varies in (0,1). We completely describe the wall crossings of these K-moduli spaces. As a consequence, we verify Laza-O'Grady-Grady's prediction on the Hassett-Keel-Looijenga program for quartic K3 surfaces. This is based on joint work with K. Ascher and K. DeVeleming.
Thurston introduced pleated surfaces as a powerful tool to study hyperbolic 3-manifolds. Passing to universal covers, a pleated surface is a map $f$ from the hyperbolic plane into hyperbolic 3-space which is a totally geodesic immersion on the complement of geodesic lamination and is equivariant with respect to a representation from the fundamental group of a hyperbolic surface into the Lie group $\text{PSL}(2,\mathbb{C})$ of orientation preserving isometries of hyperbolic 3-space.

For a fixed maximal geodesic lamination $L$, Bonahon described a holomorphic parametrization of the space of pleated surfaces with pleating locus $L$ which in turn provides a holomorphic parametrization of an open subset of the character variety of $\text{PSL}(2,\mathbb{C})$.

In this talk, we will discuss a generalization of this theory to surface group representations into $\text{PSL}(d,\mathbb{C})$. In particular, we introduce a notion of $d$-pleated surface which is motivated by the theory of Anosov representations, and we define shear-bend-eruption coordinates for these representations.

This talk is based on joint work with Sara Maloni, Filippo Mazzoli and Tengren Zhang.

With the emergence of new online channels and information technology, digital advertising tends to substitute more and more to traditional advertising by offering the opportunity to companies to target the consumers/users that are potentially interested by their products or services. We introduce a continuous time model for the study of optimal bidding strategies associated to different types of advertising, namely, commercial advertising for triggering purchases or subscriptions, and social marketing for alerting population about unhealthy behaviours (anti-drug, vaccination, road-safety campaigns). Our framework encodes users online behaviours via their web-browsing at random times, social interactions in a large population of users, and the targeted advertising auction mechanism widely used on Internet. We address the attribution problem of how to efficiently diffuse advertising information by means of digital channels in order to generate conversion. Our main results are to provide semi-explicit formulas for the optimal value and bidding policy in various contexts of commercial advertising and social marketing. We show sensitivity properties of the solution with respect to model parameters, and analyse how the different sources of digital information accessible to users including the social interactions affect the optimal bid for advertising auctions. We also study how to efficiently combine targeted advertising and non-targeted advertising mechanisms. Finally, some classes of examples with fully explicit formulas are derived.
Van Eenam Lecture Series: Optimal Bidding Strategies for Digital Advertising With Social Interactions

With the emergence of new online channels and information technology, digital advertising tends to substitute more and more to traditional advertising by offering the opportunity to companies to target the consumers/users that are potentially interested by their products or services. We introduce a continuous time model for the study of optimal bidding strategies associated to different types of advertising, namely, commercial advertising for triggering purchases or subscriptions, and social marketing for alerting population about unhealthy behaviours (anti-drug, vaccination, road-safety campaigns). Our framework encodes users online behaviours via their web-browsing at random times, social interactions in a large population of users, and the targeted advertising auction mechanism widely used on Internet. Moreau envelope of supremum functions

In this talk, we show results concerning the Moreau envelope of the supremum of a family of convex, proper, and lower semicontinuous functions. Under mild assumptions, we prove that the Moreau envelope of a supremum is the supremum of Moreau envelopes, which allows us to approximate possibly nonsmooth supremum functions by smooth regularization, which is also the suprema of continuously differentiable mappings. Consequently, we approximated optimization problems from infinite and stochastic programming for which we obtain zero-duality gap results and optimality conditions without the verification of constraint qualification conditions.

Approximate Matrix Multiplication and Laplacian Sparsifiers

A ubiquitous operation in numerical analysis and scientific computing is matrix multiplication. However, it presents a major computational bottleneck when the matrix dimension is high, as can occur for large data size or feature dimension. A common approach in approximating the product, is to subsample row vectors from the two matrices, and sum the rank-1 outer products of the sampled pairs. We propose a sampling distribution based on the leverage scores of the two matrices. We give a characterization of our approximation in terms of the Euclidean norm, analogous to that of a $L_2$-subspace embedding. We then show connections between our algorithm; CR-multiplication, with Laplacian spectral sparsifiers, which also have numerous applications in data science, and how approximate matrix multiplication can be used to devise sparsifiers.

On quantum ergodicity on Bruhat-Tits buildings

Quantum ergodicity refers to equidistribution of eigenfunctions of Laplace-like operators which arise from \`quantizing" an ergodic dynamical system. The original quantum ergodicity theorem was about eigenfunctions of the Laplacian in the high eigenvalue limit on a manifold with ergodic geodesic flow (such as a hyperbolic surface). More recently Anantharaman and Le Masson studied eigenfunctions of the adjacency operator on sequences of regular graphs Benjamini-Schramm converging to the tree. Inspired by these results, Le Masson and Sahlsten obtained analogous results for sequences of hyperbolic surfaces Benjamini-Schramm converging to the hyperbolic plane, and Brumley and Matz for sequences of locally symmetric spaces Benjamini-Schramm converging to the symmetric space $SL(n, R)/SO(n)$. By reinterpreting (certain) regular graphs as quotients of the Bruhat-Tits building associated to $SL(2, F)$, where $F$ is a p-adic field, a natural question is if analogous results hold for quotients of higher rank Bruhat-Tits buildings (which may be viewed as p-adic symmetric spaces). We obtain analogous results for the Bruhat-Tits building associated to $SL(3, F)$. No prior background on quantum ergodicity or buildings will be assumed in this talk.
