

POSITIVITY IN THE COHOMOLOGY OF FLAG BUNDLES (AFTER GRAHAM)

DAVE ANDERSON

In [Gr], Graham proves that the structure constants of the equivariant cohomology ring of a flag variety are positive combinations of monomials in the roots:

Theorem 1 ([Gr, Cor. 4.1]). *Let $X = G/B$ be the flag variety for a complex semisimple group G with maximal torus $T \subset B$, and let $\{\sigma_w \in H_T^* X \mid w \in W\}$ be the basis of (B -invariant) Schubert classes. Let $\{\alpha_i\}$ be the simple roots which are negative on B . Then in the expansion*

$$\sigma_u \cdot \sigma_v = \sum_w c_{uv}^w \sigma_w,$$

the coefficients c_{uv}^w are in $\mathbb{Z}_{\geq 0}[\alpha]$.

Graham deduces this from a more general result about varieties with finitely many unipotent orbits, which is proved using induction and a calculation in the rank-one case.

The goal of this note is to give a short, geometric proof of Graham's positivity theorem, based on a transversality argument. Here I only discuss type A , but other types work as well. (For a type-uniform version, a change of language is needed: one should replace vector bundles with corresponding principal G -bundles.)

Throughout, Fl denotes the variety of (complete) flags in \mathbb{C}^n , and if $V \rightarrow X$ is a vector bundle, $\mathbf{Fl}(V) \rightarrow X$ is the bundle of flags in V .

Recall that for $T' \cong (\mathbb{C}^*)^n$, we have $BT' = (\mathbb{P}^\infty)^{\times n}$ and $H_{T'}^* Fl = H^*(ET' \times^{T'} Fl) = H^*\mathbf{Fl}(E')$, where E' is the sum of the n tautological line bundles on BT' . The effective action on Fl is by $T \cong (\mathbb{C}^*)^n/\mathbb{C}^*$, and the classifying space for this torus is $BT = (\mathbb{P}^\infty)^{\times n-1}$. We will usually deal with the effective torus.

Let $\mathbb{P} = \mathbb{P}^m \times \cdots \times \mathbb{P}^m$ ($n-1$ factors), with $m \gg 0$, and write $H^*\mathbb{P} = \mathbb{Z}[\alpha_1, \dots, \alpha_{n-1}]$. (We always assume that m is large enough so that there are no relations in the relevant degrees.) Let $M_i = p_1^*(\mathcal{O}(-1))$ be the tautological bundle on the i th factor, and let $\alpha_i = -c_1(M_i)$. Note that the class of any effective cycle in $H^*\mathbb{P}$ is a positive polynomial in the α 's.

Let

$$L_i = M_1 \otimes \cdots \otimes M_{i-1}$$

Date: September 30, 2007.

for $1 \leq i \leq n$ (so $L_1 = \mathcal{O}$ is the trivial line bundle), and let $E_i = L_1 \oplus \cdots \oplus L_i$. Thus we have a flag E_\bullet in $E = E_n$. Let \tilde{E}_\bullet be the opposite flag, with $\tilde{E}_i = L_n \oplus \cdots \oplus L_{n+1-i}$. In the flag bundle $p : \mathbf{Fl}(E) \rightarrow \mathbb{P}$, with universal quotient flags Q_\bullet , we have Schubert loci $\Omega_w = \Omega_w(E_\bullet \rightarrow Q_\bullet)$, defined by

$$(1) \quad \Omega_w = \{x \in \mathbf{Fl}(E) \mid \text{rk}(E_p \rightarrow Q_q) \leq \#\{i \leq q \mid w(i) \leq p\}\}.$$

Opposite Schubert loci $\tilde{\Omega}_w = \Omega_w(\tilde{E}_\bullet \rightarrow Q_\bullet)$ are defined similarly. We also have ‘‘Schubert cell bundles’’ Ω_w^o : these are affine bundles over \mathbb{P} which are open in the corresponding loci Ω_w , and are defined by replacing the inequality in (1) with an equality.

The classes $[\Omega_w]$ form a basis for $H^*\mathbf{Fl}(E)$ over $H^*\mathbb{P}$, as w ranges over S_n . Writing

$$[\Omega_u] \cdot [\Omega_v] = \sum_w c_{uv}^w [\Omega_w]$$

with $c_{uv}^w \in H^*\mathbb{P}$, our main result is the following:

Proposition 2. *The polynomials c_{uv}^w are positive, that is, $c_{uv}^w \in \mathbb{Z}_{\geq 0}[\alpha_1, \dots, \alpha_{n-1}]$.*

This implies Graham’s positivity theorem (in this context), since \mathbb{P} approximates BT for m sufficiently large, and $\mathbf{Fl}(E)$ approximates $ET \times^T Fl$, with $[\Omega_w]$ corresponding to the equivariant class σ_w . (See [Fu2, §9].)

Proposition 2 is a consequence of a transversality statement:

Proposition 3. *For any $u, v, w \in S_n$, there is a translate Ω'_v of Ω_v by the action of a connected algebraic group such that Ω'_v intersects Ω_u and $\tilde{\Omega}_{w_0 w}$ properly and generically transversally.*

To deduce Proposition 2, first note that the intersection $\Omega_u \cap \tilde{\Omega}_{w_0 w}$ is always proper and generically transverse. Thus Proposition 3 says that $\Omega'_v \cap (\Omega_u \cap \tilde{\Omega}_{w_0 w})$ is proper and generically transverse. By [Fu1, Ex. (8.1.11)], this says that

$$[\Omega_v] \cdot [\Omega_u] \cdot [\tilde{\Omega}_{w_0 w}] = [\Omega'_v \cap \Omega_u \cap \tilde{\Omega}_{w_0 w}].$$

(Since $\Omega'_v = g \cdot \Omega_v$ for some g in a connected algebraic group, $[\Omega'_v] = [\Omega_v]$.) Using relative Poincaré duality (see e.g. [Fu2, §A.6]), we have

$$c_{uv}^w = p_*([\Omega_u] \cdot [\Omega_v] \cdot [\tilde{\Omega}_{w_0 w}]) = p_*([\Omega_u \cap \Omega'_v \cap \tilde{\Omega}_{w_0 w}]).$$

This is an effective class in $H^*\mathbb{P}$, so Proposition 2 follows.

Proof of Proposition 3. This is essentially an application of Kleiman’s theorem. The endomorphism bundle

$$\begin{aligned} \mathbf{End}(E) &= \bigoplus_{i,j} L_i^{-1} \otimes L_j \\ &= \left(\bigoplus_{i < j} M_i \otimes \cdots \otimes M_{j-1} \right) \oplus \mathcal{O}^{\oplus n} \oplus \left(\bigoplus_{i > j} M_j^{-1} \otimes \cdots \otimes M_{i-1}^{-1} \right) \end{aligned}$$

has global sections in lower-triangular matrices, so the group B of (invertible) lower-triangular matrices acts on $\mathbf{Fl}(E)$, fixing the flag \tilde{E}_\bullet and stabilizing $\tilde{\Omega}_{w_0 w}$. (Note that the entries of a matrix in B are global sections of the line bundles $M_j^{-1} \otimes \cdots \otimes M_{i-1}^{-1}$, i.e., multi-homogeneous polynomials. This is a connected group over \mathbb{C} , acting on a fiber $p^{-1}(x) \subset \mathbf{Fl}(E)$ by first evaluating the sections at x .)

Now let $H = (GL_{m+1})^{\times(n-1)}$, and for $b \in B$, let b_x be the evaluation at $x \in \mathbb{P}$ (so the action of b on $p^{-1}(x)$ is by b_x). Consider the semidirect product $\Gamma = B \rtimes H$, given by $(h \cdot b \cdot h^{-1})_x = b_{h^{-1} \cdot x}$. (This action of H on B is just the usual action of H on global sections of the equivariant vector bundle $\mathbf{End}(E)$.)¹ As a semidirect product of connected groups, Γ is a connected algebraic group. We claim that the locus $\tilde{\Omega}_{w_0 w}^o$ is homogeneous for the action of Γ . Indeed, B acts transitively on each fiber of $\tilde{\Omega}_{w_0 w}^o$, and the action of H on $\mathbf{Fl}(E)$ induces a transitive action on the set of fibers of $\tilde{\Omega}_{w_0 w}^o$. (The line bundles L_i are equivariant for H , so H preserves the flag \tilde{E}_\bullet , and therefore acts on $\tilde{\Omega}_{w_0 w}^o$.)

Finally, note that Ω_u^o and $\tilde{\Omega}_{w_0 w}^o$ intersect transversally, as do Ω_v^o and $\tilde{\Omega}_{w_0 w}^o$. The proposition follows from Lemma 4 below, taking $U = \Omega_u$, $V = \Omega_v$, and $W = \tilde{\Omega}_{w_0 w}$, with their stratifications by Schubert loci. \square

Lemma 4. *Let X be a nonsingular variety over a field of characteristic 0, with an action of a connected algebraic group Γ . Let $U, V, W \subset X$ be subvarieties with stratifications*

$$\begin{aligned} U_0 &\subset \cdots \subset U_\ell = U, \\ V_0 &\subset \cdots \subset V_m = V, \\ W_0 &\subset \cdots \subset W_n = W, \end{aligned}$$

with each stratum $U_i \setminus U_{i-1}$ nonsingular. Assume also that Γ acts on W , with each stratum $W_i \setminus W_{i-1}$ a disjoint union of homogeneous spaces.

If $U_i \setminus U_{i-1}$ meets $W_k \setminus W_{k-1}$ transversally for all i, k , and similarly for $V_j \setminus V_{j-1}$ and $W_k \setminus W_{k-1}$, then there is an element $g \in \Gamma$ such that $g \cdot V$ meets $U \cap W$ properly and generically transversally.

This can be deduced from results found in [Sp]; see also [Si] for a vast generalization. The proof of this version is quite short, so we give it here.

Proof. Applying Kleiman's theorem (cf. [Ha, III.10.8]) to the pairs $(U_i \setminus U_{i-1} \cap W_k \setminus W_{k-1})$ and $(V_j \setminus V_{j-1} \cap W_k \setminus W_{k-1})$ inside the homogeneous space $W_k \setminus W_{k-1}$, we can choose $g \in \Gamma$ such that each intersection

$$\begin{aligned} &(U_i \setminus U_{i-1} \cap W_k \setminus W_{k-1}) \cap g \cdot (V_j \setminus V_{j-1} \cap W_k \setminus W_{k-1}) \\ &= (U_i \setminus U_{i-1} \cap W_k \setminus W_{k-1}) \cap (g \cdot V_j \setminus g \cdot V_{j-1} \cap W_k \setminus W_{k-1}) \end{aligned}$$

¹Alternatively, one could take Γ to be the subgroup of $\text{Aut}(\mathbf{Fl}(E))$ generated by the images of B and G via the homomorphisms corresponding to their respective actions.

is transverse, so the intersection $U \cap W \cap g \cdot V$ is proper and generically transverse. \square

Remark 5. All that is required in the proof of Proposition 3 are the facts that \mathbb{P} is homogeneous for the action of an algebraic group H , and L_i are H -equivariant line bundles such that $L_i^{-1} \otimes L_j$ is globally generated for $i > j$.

Remark 6. To recover the result that for (type A) equivariant Schubert calculus, the structure constants c_{uv}^w are in $\mathbb{Z}_{\geq 0}[t_2 - t_1, \dots, t_n - t_{n-1}]$, let $\mathbb{P}' = (\mathbb{P}^{m'})^{\times n}$ and choose a map $\varphi : \mathbb{P}' \rightarrow \mathbb{P}$ such that $\varphi^* M_i = M'_i \otimes (M'_{i+1})^{-1}$, where M'_i is the tautological bundle on the i th factor of \mathbb{P}' , with $t_i = c_1(M'_i)$. (Note that φ will not be holomorphic!)

The T' -equivariant class of a Schubert variety (for $T' = (\mathbb{C}^*)^n$) can be identified with the class of the locus $\Omega_w(E'_\bullet \rightarrow Q_\bullet) \subset \mathbf{Fl}(E')$, where $E'_i = M'_1 \oplus \dots \oplus M'_i$ is a flag of bundles on \mathbb{P}' . Since this is $\varphi^{-1} \Omega_w$, the equivariant structure constants are $\varphi^* c_{uv}^w$, which are positive in the variables $\varphi^* \alpha_i = t_{i+1} - t_i$.

Remark 7. The naive choice of flag, with $F_i = M_1 \oplus \dots \oplus M_i$, does not work: The bundle $\mathbf{End}(F)$ has only diagonal global sections, so the corresponding loci Ω_w^o are not homogeneous. This explains why one does not see positivity over \mathbb{P}' .

Acknowledgements. This proof was inspired by William Fulton's lectures on equivariant cohomology [Fu2], and I thank him for comments on the manuscript. Thanks also to Sue Sierra for interesting discussions, and for bringing [Sp] to my attention.
