On the Fourier coefficients of modular forms of half-integral weight

Kartik Prasanna
(Communicated by Peter Sarnak)

Abstract. We prove a formula relating the Fourier coefficients of a modular form of half-integral weight to the special values of $L$-functions. The form in question is an explicit theta lift from the multiplicative group of an indefinite quaternion algebra over $\mathbb{Q}$. This formula has applications to proving the nonvanishing of this lift and to an explicit version of the Rallis inner product formula.

1 Introduction

The origins of this article lie in a remarkable proportionality relation discovered by Waldspurger [12] between the squares of the Fourier coefficients of a half-integral weight modular form $h$ and special values of $L$-functions attached to the Shimura lift $f$ of $h$. Recently, by a different method (namely Jacquet’s relative trace formula), Baruch and Mao (generalizing results of Kohnen-Zagier [2], Kohnen [1] etc.) have established in some cases a more precise relation between the squares of the absolute values of the Fourier coefficients and...
special values, thus computing the absolute value of the proportionality constant occurring in Waldspurger’s work.

The aim of this article is to establish yet another formula (see Thm. 1.1 below) for the squares of the absolute values of Fourier coefficients of a certain explicitly constructed half-integral weight form. This formula has several applications. Firstly, it can be used to show that a certain explicit theta lift, from $PB^\times$ to $SL_2$, for $B$ an indefinite quaternion algebra over $Q$, is nonvanishing. Secondly, combining this formula with the formula of Baruch-Mao mentioned above, one may obtain a completely precise version of the Rallis inner product formula (see [7] Sec. 7.1) for certain theta lifts from $SL_2$ to $PB^\times$. Both Thm. 1.1 and this explicit version of the Rallis inner product formula are crucial ingredients in the forthcoming articles [7], [8], on the arithmetic properties of the theta correspondence and the $p$-adic properties of central $L$-values of quadratic twists of elliptic curves. Since the relation between the formulae above may be somewhat confusing, we remark that it is explained by the diagram below, in which any two of the formulae imply the third.

\begin{equation}
\text{Thm. of Baruch-Mao} \leq \rightarrow \text{Rallis inner product formula}
\end{equation}

To explain the statement of Thm. 1.1, we need some notation. Let $f$ be a holomorphic modular form of weight $2k$, trivial central character and odd squarefree level $N$. Let $\chi$ be a finite order character of conductor $N'$ dividing $4N$, and suppose $\tau = 0$ or 1 is such that $\chi = \chi \cdot (\frac{-1}{\cdot})^{k+\tau}$ is unramified at 2. Set $\chi_0 = \chi \cdot (\frac{-1}{\cdot})^k$. Also let $w_q$ be the sign of the Atkin-Lehner involution attached to $f$ at $q$. Denote by $\pi$ the automorphic representation of $PGL_2(A)$ attached to $f$ and let $f_\chi$ be a newform in $\pi \otimes \chi$ normalized to have its first Fourier coefficient equal to 1.

Suppose that $B$ is an indefinite quaternion algebra of discriminant $N^- | N$ and denote by $g_\chi$ a newform in $\pi' \otimes \chi$ where $\pi'$ is the Jacquet-Langlands lift of $\pi$. Let $\nu$ be an odd fundamental quadratic discriminant satisfying $\text{sign}(\nu) = (-1)^\tau$ as well as

\begin{align}
(1.1) \quad (a) & \quad \text{If } q | N, q \nmid \nu, \chi_0q(-1) = \alpha_q \chi_{\nu q}(q) w_q. \\
& \quad \text{(b) If } q | N, q \nmid \nu, \chi_0q(-1) = \alpha_q.
\end{align}

where $\alpha_q = (\frac{b}{q})$. In case (b) we also assume for simplicity that $\chi_0q$ is ramified exactly when $q | N^-$. Let $V = \{x \in B | \text{tr}(x) = 0\}$ and $\varphi \in \mathcal{S}(V(A))$ the Schwartz function defined in Sec. 3.2 of [7]. Put $s = s_{\varphi} \otimes (\chi^{-1} \chi_0) \in \pi' \otimes \chi_0$, $\psi' = \psi^{\nu/|\nu|}$ where $\psi$ is the usual additive character on $Q \setminus A_Q$. Finally, denote by $h$ the theta lift $h := \theta(\psi', \varphi, s)$ on $SL_2(A)$. Then we have

\textbf{Theorem 1.1.} (1) $h \in S_{k+\frac{1}{2}}(M, \chi)$ where $M = \text{lcm}(NN', 4)$.

(2) Let $\xi$ be any positive integer and set $\xi_0 := (-1)^\tau \xi$. Then $a_\xi(h) = 0$ unless the following conditions are satisfied:

\begin{itemize}
  \item[(a)] $q \nmid \nu$.
  \item[(b)] $q | N, q \nmid \nu, \chi_0q(-1) = \alpha_q$. \quad \text{with } \chi_0q(n) = 1.
\end{itemize}
We now explain briefly the idea of the proof. The Fourier coefficient in question is readily expressible as a sum of integrals of \( g_\chi \) against certain characters of real quadratic tori \( K^{\times} \hookrightarrow B^{\times} \). One shows first that up to an explicit scalar, it is in fact equal to a single such toric integral. Next one applies a method of Waldspurger (from his article [13]) to show that the absolute value squared of this torus integral is given by the \( L \)-value above. This method is now quite familiar and has been exploited in the recent articles [6], [5], [16] to relate period integrals along tori and \( L \)-values. The case of real quadratic fields has been worked out in detail in Popa’s article [5] with some assumptions on the local ramification. However the particular problem that confronts us is different in two aspects described below, which lends to the novelty of this article.

Firstly, the articles [5], [16] express an \( L \)-value as a period integral, for some convenient choice of embedding \( j : K^{\times} \hookrightarrow B^{\times} \). In our case, it is not the \( L \)-value but the period integral that appears in the arithmetic theory of the theta correspondence, and one must prove a formula relating it to the \( L \)-value in question. Consequently, one cannot make a convenient choice of embedding \( j \); instead we need to deal systematically with all the different possibilities for \( j \) that occur naturally in the formulae for the Fourier coefficients of the theta lift. This leads to the second main difference, namely that we need to consider several more possibilities as regards the local ramifications in the ramified zero integrals than are dealt with in the articles cited above.

We remark that it would be very useful to have a general formula for \( B \) a quaternion algebra over an arbitrary number field \( K \), relating the period integral of a newform on \( B \) to an \( L \)-value for any choice of \( j : K \hookrightarrow B \) (\( K \) quadratic over \( F \)) and for all possible choices of local ramification. By Waldspurger’s formula this is a purely local issue involving computations of ramified zero integrals. Yet, in that generality, it would be significantly more complicated than the few cases considered in this article.

The present article is organized as follows. In Section 2.1, we set up the main theme of this article, namely a certain explicit theta lift from \( PB^\times \) to \( \tilde{SL}_2 \), and in Section 2.2, derive a formula relating the Fourier coefficients of this lift to certain integrals along tori. Next, we recall in Section 3 the method of Waldspurger to compute the squares of absolute values of such period integrals using the dual pair \((\text{GL}_2, \text{GO}(B))\). This method expresses these integrals in terms of certain \( \chi \)-values. The case of real quadratic fields has been worked out in detail in Popa’s article [5] with some assumptions on the local ramification. However the particular problem that confronts us is different in two aspects described below, which lends to the novelty of this article.

Firstly, the articles [5], [16] express an \( L \)-value as a period integral, for some convenient choice of embedding \( j : K^{\times} \hookrightarrow B^{\times} \). In our case, it is not the \( L \)-value but the period integral that appears in the arithmetic theory of the theta correspondence, and one must prove a formula relating it to the \( L \)-value in question. Consequently, one cannot make a convenient choice of embedding \( j \); instead we need to deal systematically with all the different possibilities for \( j \) that occur naturally in the formulae for the Fourier coefficients of the theta lift. This leads to the second main difference, namely that we need to consider several more possibilities as regards the local ramifications in the ramified zero integrals than are dealt with in the articles cited above.

We remark that it would be very useful to have a general formula for \( B \) a quaternion algebra over an arbitrary number field \( K \), relating the period integral of a newform on \( B \) to an \( L \)-value for any choice of \( j : K \hookrightarrow B \) (\( K \) quadratic over \( F \)) and for all possible choices of local ramification. By Waldspurger’s formula this is a purely local issue involving computations of ramified zero integrals. Yet, in that generality, it would be significantly more complicated than the few cases considered in this article.

The present article is organized as follows. In Section 2.1, we set up the main theme of this article, namely a certain explicit theta lift from \( PB^\times \) to \( \tilde{SL}_2 \), and in Section 2.2, derive a formula relating the Fourier coefficients of this lift to certain integrals along tori. Next, we recall in Section 3 the method of Waldspurger to compute the squares of absolute values of such period integrals using the dual pair \((\text{GL}_2, \text{GO}(B))\). This method expresses these

---

* In fact, with a little more care, our proof can easily be modified to prove a formula for the squares of the Fourier coefficients and not just their absolute values.
quantities as the value at 1/2 of a certain global zeta integral. In Sec. 4 we compute the
development of this subject. The results are put together in Sec. 5 to obtain the final formula of Thm. 1.1.

2 Fourier coefficients and toric integrals

2.1 Ternary forms: the dual pair ($\widetilde{SL}_2$, $PB^*$) and the basic setup

The reader is referred to the introduction and [7] §2.1 for the notation used below. We recall
first some facts about the Weil representation. Let $W$ be a two dimensional symplectic vector
space. The metaplectic cover $\text{Sp}(W \otimes V)$ splits over the orthogonal group $O(V)$ which is
identified with $PB^* \times \langle c \rangle$, where $\langle c \rangle$ is the cyclic group of order 2 generated by the main
involution and the action of $\beta \in PB^*$ on $V$ is given by $\beta \cdot (x) = \beta x \beta^{-1}$. Let $\tilde{S}_e$ (resp. $\tilde{S}_e$)
denote the twofold metaplectic cover of $SL_2(\mathbb{Q}_e)$ (resp. $SL_2(\mathbb{A}_e)$). Then for each place $v$ of
$\mathbb{Q}$, the Weil representation of $\text{Sp}(W \otimes V)_v$ yields by restriction a representation of $\tilde{S}_e \times PB^*_v$
on $\mathcal{F}_\varphi(V \otimes \mathbb{Q}_v)$ denoted $\omega_{\varphi}$. The restriction of $\omega_{\varphi}$ to $\tilde{S}_e$ is a genuine representation of $\tilde{S}_e$, denoted $r_{\varphi}$, satisfying

\begin{align}
(2.1) \quad r_{\varphi}(n)\varphi(x) &= \psi'(nQ(x))\varphi(x) \\
(2.2) \quad r_{\varphi}(d(a))\varphi(x) &= \mu_{\varphi}(a)(a,1)_v|a|^{3/2}\varphi(ax) \\
(2.3) \quad r_{\varphi}(w,\epsilon)\varphi(x) &= \epsilon_\gamma\varphi_{\omega}^{\nu}\mathcal{F}_{\varphi}(\varphi)
\end{align}

where we write $\psi'$ instead of $\psi'$. The Haar measure on $V \otimes \mathbb{Q}_v$ is picked to be autodual
with respect to the pairing $(x_1, x_2) \mapsto \psi'(\langle x_1, x_2 \rangle)$. In future we will write $\mathcal{F}(\varphi)$ for $\mathcal{F}_\varphi(\varphi)$. Thus $\omega_{\varphi}(\sigma, \beta) = r_{\varphi}(\sigma)R(\beta)$ where $R(\beta)\varphi(v) = \varphi(\beta^{-1}v\beta)$.

Let $\mathcal{A}'_0$ and $\tilde{\mathcal{A}}_0$ denote the spaces of cusp forms on $PB^*(\mathbb{A})$ and $\tilde{S}_A$ respectively. For $s \in \mathcal{A}'_0$, $\varphi \in \mathcal{F}_{\varphi}(V_\mathbb{A})$, define

$$
\theta(\psi', \varphi, \sigma, \beta) = \sum_{s \in \mathcal{A}} r_{\psi}(\sigma)R(\beta)\varphi(x)
$$

$$
t(\psi', \varphi, \sigma, s) = \int_{PB^* \times PB^*_\mathbb{A}} \theta(\psi', \varphi, \sigma, \beta)s(\beta)\beta
$$

where the measure is the usual Tamagawa measure. We now choose $s$ as in the introduction
and $\varphi = \prod_v \varphi_v$ to be the Schwartz function defined in Sec. 3.2 of [7]. It is shown then
in [7], Prop. 3.4 that $t_{\psi'}(\epsilon, \sigma, s) = t_{\psi}$ for a unique $h \in S_{k+1}(M, \chi)$.

We recall now some additional notation defined in [7] that we will need. Let $\mathcal{O}_N$ be
an Eichler order of level $N^+$ in $B$. Let $\mathcal{O}'(\chi)$ be the unique Eichler order in $B$ such that
$\mathcal{O}'(\chi) \otimes \mathbb{Z}_q = \mathcal{O}_N \otimes \mathbb{Z}_q$, unless $q | N'$ and $q \nmid N^+$, in which case

$$
\phi_q(\mathcal{O}'(\chi) \otimes \mathbb{Z}_q) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2(\mathbb{Z}_q), c \equiv 0 \mod q^2 \right\},
$$
On the Fourier coefficients of modular forms of half-integral weight

and define open compact subgroups \( U_0, U_0(\chi) \subseteq B_\chi \) by

1. \( U_0 = \prod_q U_{0,q} \) where \( U_{0,q} = (\mathbb{O}_N \otimes \mathbb{Z}_q)^\times \).
2. \( U_0(\chi) = \prod_q U_{0,q}(\chi) \), where \( U_{0,q}(\chi) = (\mathcal{O}'(\chi) \otimes \mathbb{Z}_q)^\times \).

We define below a character \( \tilde{\omega}_\chi \) on \( U_{0,q}(\chi) \) such that \( \tilde{\omega}_\chi | Z_\chi = \chi^2 \). Firstly, for each \( q \) define \( \tilde{\omega}_{X,q} \) on \( U_{0,q}(\chi) \) as follows:

- For \( q \mid N_\chi \), \( \tilde{\omega}_{X,q}(u) = 1 \).
- For \( q \mid N_\chi \) and \( q \mid N'^+ \), \( \tilde{\omega}_{X,q}(u) = \chi_q(d)^2 \) for \( u = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \).
- For \( q \mid N_\chi \) and \( q \mid N'^- \), \( \tilde{\omega}_{X,q}(u) = \chi_q(Nm(u)) \).

Then, set \( \tilde{\omega}_\chi = \prod_q \tilde{\omega}_{X,q} \) on \( U_{0,q}(\chi) \). Now let \( \Gamma' \) (resp. \( \Gamma_\chi \)) be the group of norm 1 units in \( \mathbb{O}_2 \) (resp. \( \mathcal{O}'(\chi) \)) and define \( \chi' \) to be the restriction of \( \tilde{\omega}_\chi^{-1} \) to \( \Gamma' \subseteq U_0 \).

### 2.2 Integrals along tori and Fourier coefficients of the theta lift

We would like to write down a formula that expresses the Fourier coefficients of \( h \) as a sum of period integrals. It is convenient to begin with some generalities. Let \( \mathcal{O}' \) be an order in \( B, \mathcal{U} \) the open compact subgroup of \( B_{\mathcal{O}_2} \) given by \( \mathcal{U} = \prod_q U_{\mathcal{O}' q} \), \( U_{\mathcal{O}' q} = (\mathcal{O}' \otimes \mathbb{Z}_q)^\times \). Let \( \Gamma' = B_\chi \cap \Gamma(\mathcal{U}_{\mathcal{O}' q}) \), \( \hat{\omega} \) be a character of \( \mathcal{U} \) and set \( \omega' = \hat{\omega}^{-1} | \Gamma' \). Suppose \( g' \in S_{2k}(\Gamma', \omega') \) and \( s_{g'} \in \tilde{S}_{2k}(\mathcal{U}', \hat{\omega}) \) is the corresponding adelic modular form. Let \( \omega \) be the unique finite order character of \( Q_2^\times \) such that \( \hat{\omega} | U \otimes Q_2^\times = \omega | U \otimes Q_2^\times \). Thus the central character of \( s_{g'} \) is \( \omega \).

For \( \nu \in \mathbb{C} \) and \( \alpha \in V \otimes \mathbb{R} \), define

\[
[\alpha, \nu] = \begin{pmatrix} \nu & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \nu & 1 \\ 0 & 1 \end{pmatrix}^{-1} = c\nu^2 - 2bw + a
\]

if \( \alpha = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \).

For \( x \in V \), let \( G_x = \{ h \in SL_2(\mathbb{R}) \mid h^{-1} x h = x \} \), \( I'_{\chi} \) and \( I_{\chi} \) be the trivial character. Then we may define (as in [9] (2.5); see same reference for normalization of measures)

\[
P(g', x, I') = \int_{I'_{\chi}(G_x)} [x, hw]^k g'(hw)d(\Gamma'_{\chi}h)
\]

for any \( w \in \mathcal{O}_2 \), since the condition \( \omega'| I'_{\chi} = 1 \) implies that the integrand is \( I'_{\chi} \) invariant. Denote by \( V^* \) the set of \( x \in V \) such that \( Nm(x) < 0 \). By [9] Lemma 2.1, \( P(g', x, I') \) is independent of the choice of \( w \) and is equal to 0 unless \( x \in V^* \). Let \( R(\Gamma') \) be the set of equivalence classes in \( V^* \) for the conjugation action of \( \Gamma' \) and for \( \ell \in R(\Gamma') \), set \( Q(\ell) = -Nm(x) \) for any choice of \( x \in \ell \). By [9] (2.6), \( P(g', x, I') \) only depends on the class of \( x \) in \( R(\Gamma') \). Thus for \( \ell \in R(\Gamma') \) we may set \( P(g', \ell, I') = P(g', x, I') \) for any choice of \( x \in \ell \).

Let \( F \) be any real quadratic field that embeds in \( B, j : F \hookrightarrow B \) an embedding, \( \eta \) a finite order character of \( F_2^\times \) such that \( \eta|Q_2^\times = \omega^{-1} \) and suppose that \( \omega_\infty \) is the trivial character.
The assumption

\[ \eta = \omega^{-1} \] (resp. that \( \omega \) is the trivial character) ensures that the integrand above is \( Q^\times \) invariant (resp. that the integral is independent of the choice of \( \gamma_\infty \)). Here we pick our measure conventions to match those of \([5]\).

Suppose \( C' \cap F = \mathbb{Z}+\mathbb{Z} \delta \), where \( \mathbb{Z}+\mathbb{Z} \delta \) is the maximal order of \( F \). Let \( C_{F,\mathcal{E}} = \mathbb{Z}+\mathbb{Z} \delta \), and \( U_{F,\mathcal{E}} \) be the open compact in \( F^\mathbb{A}_F \) given by \( U_{F,\mathcal{E}} = \tilde{\mathcal{O}}_{F,\mathcal{E}}^\times \), so that \( s_{\mathcal{E}}(x) \) and \( \eta(x) \) are invariant under \( U_{F,\mathcal{E}} \). Let \( x_i \in F^\mathbb{A}_F \) be such that

\[
F^\mathbb{A}_F = \bigcup_{i=1}^{h'} F^\times \cdot U_{F,\mathcal{E}} \cdot (F_\infty^\mathbb{A})_{x_i}, \quad h' = [F^\mathbb{A}_F : F^\times U_{F,\mathcal{E}} F_\infty^\mathbb{A}]
\]

and suppose

\[
j(x_i) = \gamma_i g U', \quad g \in B^\times, \quad g U' \in U', \quad \gamma_i \in (B_\infty^\times)^+, \quad \gamma_i = g_i.
\]

Then

\[
\text{vol}(U_{F,\mathcal{E}})^{-1}L_{\eta,j}(g') = \sum_{i=1}^{h'} \eta(x_i) \tilde{\omega}_\chi(g U') \int_{(F_{\mathcal{E}}^\mathbb{A} \cap U_{F,\mathcal{E}} \cap (Q^\times))(F_\mathbb{A}^\mathbb{A})} s_{\mathcal{E}}(\gamma_i x \gamma_\infty) d^\times x
\]

\[= (-2\alpha')^{-k} \sum_{i=1}^{h'} \eta(x_i) \tilde{\omega}_\chi(g U') P(g', j(\alpha')^{i}, \Gamma''), \quad \alpha' \text{ any nonzero element of } F \text{ with trace } 0, \quad j(\alpha')^{i} = \gamma_i^{-1} j(\alpha') \gamma_i \text{ and } t = \sqrt{-1}.
\]

We now specialize our discussion to the case of interest, namely \( g' = g \chi, \quad F = Q(\sqrt{\nu}) \), \( \eta = (\chi \nu \chi)^{-1} \circ N_{F/Q}, \quad \omega' = \chi', \quad \tilde{\omega} = \tilde{\omega}_\chi, \quad \omega = \chi^2 \). Note that

\[
\varphi_{\mathcal{E}}(j(\alpha)^{i}) = \varphi_{\mathcal{E}}((\gamma_i^{-1} j(\alpha)) \gamma_i) = \varphi_{\mathcal{E}}(g U', j(x_i)x_i)^{-1} j(\alpha)(x_i) g U',
\]

\[= \varphi_{\mathcal{E}}(g U', j(\alpha) g U') = (\tilde{\omega}_\chi \cdot (\chi \nu \chi)^{-1}(g U')) \varphi_{\mathcal{E}}((\chi \nu \chi)(g U'))
\]

since \( (\chi \nu \chi)^{-1}(N m(g U')) = (\chi \nu \chi)^{-1}(N m(g U')) \). Thus

\[
\text{vol}(U_{F,\mathcal{E}})^{-1} \varphi_{\mathcal{E}}(j(\alpha')) L_{\eta,j}(g') = (-2\alpha')^{-k} \sum_{i=1}^{h'} \varphi_{\mathcal{E}}(j(\alpha')^{i}) P(g', j(\alpha')^{i}, \Gamma'').
\]
On the Fourier coefficients of modular forms of half-integral weight

It is shown in Sec. 4.2 of [7] that \( a_\xi(h) = C \cdot |\nu\xi|^{-1/2} S \) where \( C = 6[U_0 : U_0(\chi)]^{-1} \prod_{q \mid N+} (q + 1)^{-1} \prod_{q \mid N-} (q - 1)^{-1} \) and

\[
S = \sum_{\xi \in \mathcal{G}(\chi), \xi = \nu\xi} \varphi_{\text{fin}}(x) P(g_\chi, x, \Gamma_\chi)
\]

where \( x \) is any element of \( \mathcal{C} \). For a fixed class \( \mathcal{C} \), the choice of \( x \in \mathcal{C} \) yields an embedding of \( F = \mathbb{Q}(\sqrt{\nu\xi}) \) in \( B \) sending \( \sqrt{\nu\xi} \) to \( x \). A different choice of \( x \), say \( x' \in \mathcal{C} \), corresponds to an embedding that is conjugate to the original one by an element of \( \Gamma_\chi \). Suppose \( |\nu|\xi = d^2 \xi' \) where \( \xi' \) is square-free, so that \( F = \mathbb{Q}(\sqrt{\xi'}) \) and that the embedding corresponding to \( x \) has conductor \( c \). Then the conductor of the embedding corresponding to \( x' \) is also \( c \), and hence we say that the conductor of \( \mathcal{C} \) is \( c \). Conversely, given any \( \Gamma_\chi \)-conjugacy class of embeddings of conductor \( c \), one has \( \mathcal{C}' \cap F = \mathbb{Z} + \mathbb{Z}\delta \) and \( j(d\sqrt{\xi'}) \) is an element of \( V \), the class of which satisfies \( Q(\epsilon) = d^2 \xi' = |\nu\xi| \).

For \( \xi' \) square-free, let \( R(\Gamma', \mathcal{C}, d, \xi') \) denote the set of \( \mathcal{C} \in R(\Gamma') \) such that \( Q(\epsilon) = d^2 \xi' \) and that have conductor \( c \). There is a natural action of \( B_{\mathcal{A}'}^\times \) on \( \bigcup_{\mathcal{C}} R(\Gamma', \mathcal{C}, d, \xi') \), that may be described as follows: for \( g \in B_{\mathcal{A}'}^\times \), write \( g = \gamma \cdot u \) with \( \gamma \in B_{\mathcal{A}'}, u \in U' \) and define \( \mathcal{C} \mathcal{C}' = \mathcal{C} \gamma^{-1} \mathcal{C} \gamma \). This is easily seen to be independent of the choice of decomposition \( g = \gamma \cdot u \).

Indeed, if \( g = \gamma \cdot u = \gamma_1 \cdot u_1 \), then \( \delta = \gamma_1^{-1} \gamma \in \Gamma' \), and \( \delta^{-1}(\mathcal{C} \gamma^{-1} \mathcal{C} \gamma) \delta = \gamma^{-1} \mathcal{C} \gamma \). Clearly \( \mathcal{C} \mathcal{C}' = \mathcal{C} \) for any \( u \in U' \).

Let \( \hat{O}_{c, \mathcal{C}} = \mathbb{Z} + c\mathbb{Z}\delta \subset \mathbb{Q}(\sqrt{\xi'}) \). The Picard group of \( \hat{O}_{c, \mathcal{C}} \), \( \text{Pic}(\hat{O}_{c, \mathcal{C}}) \) is identified naturally with \( \hat{O}_{c, \mathcal{C}} \setminus F_{\mathcal{A}'}^\times / F_{\mathcal{A}'}^\times \), hence acts (freely) on \( R(\Gamma', \mathcal{C}, d, \xi') \) via \( \mathcal{C} \mapsto \mathcal{C}(\iota) \). Let \( \hat{R}(\Gamma', \mathcal{C}, d, \xi') \) denote the set of equivalence classes for this action. Then

\[
S = \sum_{c} \sum_{\mathcal{C} \in \hat{R}(\Gamma', \mathcal{C}, d, \xi')} \sum_{\epsilon \in \mathcal{C}} \varphi_{\text{fin}}(x) P(g_\chi, x, \Gamma_\chi)
\]

\[
= (-2\alpha')^k \sum_{\mathcal{C}} \sum_{\epsilon \in \mathcal{C}} \varphi_{\text{fin}}(j(\epsilon' \alpha' \mathcal{C})) L_{\eta, j}(\chi_\chi)
\]

where \( \alpha' = d\sqrt{\xi'} \) and \( \mathcal{C} \) is any element in \( \mathcal{C} \). Note that the value of the expression \( \varphi_{\text{fin}}(j(\epsilon' \alpha' \mathcal{C})) L_{\eta, j}(\chi_\chi) \) is independent of the choice of \( \mathcal{C} \in \mathcal{C} \).

**Proposition 2.1.** If \( L_{\eta, j}(\chi_\chi) \neq 0 \), the following conditions must be satisfied at all \( q \mid N \):

(a) If \( \chi_0, q(-1) = 1 \), then \( \left( \frac{\chi_0, q}{q} \right) = -w_q \).

(b) If \( \chi_0, q(-1) = -1 \), then \( \left( \frac{\chi_0, q}{q} \right) = \chi_0, q(-1) w_q \).

**Proof.** Fix \( q \mid N \) and let \( \epsilon_F \) denote the quadratic character corresponding to \( F \). By the main result of [10], \( \epsilon_F \equiv 0 \), \( \epsilon_F(1/2, \pi_F, \rho \otimes \eta) = \alpha_q \), where \( \pi_F \) denotes the base change of \( \pi_F \) to \( F \) and \( \epsilon_q(1/2, -) \) denotes the epsilon factor at \( q \). For simplicity, we omit the subscript \( q \) below. Define \( \gamma_a = \pm 1 \) by \( \epsilon(1/2, \pi_F \otimes \chi_a) = \gamma_a \chi_a(-1) \epsilon(1/2, \pi_F) \) (where again, by \( \chi_a \)
The proposition readily follows from (i) – (iv).

\[ \varepsilon(1/2, \pi_{f, F} \otimes \eta) = \varepsilon (1/2, \pi_{f} \otimes \text{Ind}_{\eta}^{\mathbb{Q}} \eta) \]

we mean \( \chi_{a,q} \) etc.) Then

\[ \varepsilon (1/2, \pi_{f} \otimes \text{Ind}_{\eta}^{\mathbb{Q}} \eta) = \chi_{\varepsilon \xi_{q}}(-1) e(1/2, \pi_{f} \otimes (\chi \nu \chi^{-1}) e(1/2, \pi_{f} \otimes (\chi \nu \chi^{-1} \varepsilon_{F})) \]

\[ = \chi_{\varepsilon \xi_{q}}(-1) e(1/2, \pi_{f} \otimes \nu \chi_{q}) e(1/2, \pi_{f} \otimes \chi_{q}) \]

\[ = \chi_{\varepsilon \xi_{q}}(-1) \cdot \nu_{0} \chi_{q}(-1) e(1/2, \pi_{f}) \cdot \chi_{\xi_{q}}(-1) \chi_{\varepsilon_{F}} e(1/2, \pi_{f}) \]

\[ = \nu_{0} \gamma_{\xi_{q}}. \]

We now consider four cases (and use (1.1) as well as Lemma 3.1 of [7]):

(i) If \( q \nmid \nu, q \nmid \xi, \gamma_{\nu} = \chi_{\nu}(q), \gamma_{\xi_{q}} = \chi_{\xi_{q}}(q), \chi_{\nu}(q) = \alpha \chi_{0}(-1) w \left( \frac{\ell}{q} \right), \) whence \( \left( \frac{\ell}{q} \right) = \chi_{0}(-1) w. \)

(ii) If \( q \nmid \nu, q \nmid \xi, \gamma_{\nu} = \chi_{\nu}(q), \gamma_{\xi_{q}} = w, \chi_{\nu}(q) = \alpha \chi_{0}(-1) w, \) whence \( \chi_{0}(-1) = 1 \) and \( \left( \frac{\ell}{q} \right) = 0. \)

(iii) If \( q \mid \nu, q \nmid \xi, \gamma_{\nu} = w, \gamma_{\xi_{q}} = \chi_{\xi_{q}}(q), \chi_{0}(-1) = \alpha, \) whence \( \left( \frac{\ell}{q} \right) = \chi_{0}(-1) w. \)

(iv) If \( q \mid \nu, q \mid \xi, \gamma_{\nu} = w, \gamma_{\xi_{q}} = w, \chi_{0}(-1) = \alpha. \) Hence \( \chi_{0}(-1) = 1 \) and \( \left( \frac{\ell}{q} \right) = 0. \)

The proposition readily follows from (i) – (iv).

**Proposition 2.2.** If \( S \neq 0, \) then the following conditions must be satisfied at all \( q \mid N: \)

(a) For all \( q \mid N, q \nmid N', \left( \frac{\ell}{q} \right) \neq -w_{q}. \)

(b) For all \( q \mid N', \left( \frac{\ell}{q} \right) = \chi_{0,q}(-1) w_{q}. \)

(c) \( \xi_{q} \equiv 0, 1 \mod 4. \)

**Proof.** Part (c) follows immediately from the definition of the Schwartz function \( \varphi_{x}. \) By the previous proposition, to prove parts (a) and (b), it suffices to show that \( S = 0 \) if there exists \( q \mid N' \) such that \( q \nmid \xi \) and \( \chi_{0,q}(-1) = 1. \) In this case \( q \nmid \nu \) by (iv) of the previous proposition and the assumption (following (1.1) in the introduction) that \( \chi_{0,q} \) is unramified if \( q \nmid N', q \nmid \nu. \)

If further \( q \mid N^{+}, \) we are in case (c2) of the definition of \( \varphi. \) Let \( \mathcal{O}_{1} \) be the Eichler order of level \( q, \left( \frac{2}{q}, \frac{2}{q} \right) = 1. \) Then \( S \) is a linear combination of terms of the form

\[ (2.4) \quad S' = \sum_{u \in \mathcal{O}_{1} \cap \mathcal{C}^{\times}_{q}} \varphi_{u} \varphi_{\nu}^{(\alpha)(\nu)} L_{\eta_{j}, \varphi_{\nu}^{(\alpha)}(g_{\chi})}. \]

It is thus enough to show that the expression (2.4) equals 0. Note that the character \( \tilde{\omega}_{\chi} \)

can be extended to \( \mathcal{C}^{\times}_{1} \) by defining \( \tilde{\omega}_{\chi} \left( \frac{a}{c} \right) = \chi_{0}(d). \) Thus \( \chi' \) extends too to the group \( \Gamma_{1} = (\prod_{j \neq q} U_{0}(\chi) \times \mathcal{C}^{\times}_{j}) \cap B^{\times}. \) Now a set of representatives for \( \mathcal{C}^{\times}_{1} \) is \( \left\{ \left( \frac{1}{j} \right) \right\} \), \( j = 0, 1, \ldots, q - 1. \) For \( u' \in \mathcal{C}^{\times}_{1}, \) write \( u' = \gamma_{u} \cdot u \) where \( \gamma_{u} \in B^{\times} \) and \( u \in U_{0}(\chi), \)
On the Fourier coefficients of modular forms of half-integral weight

so that \( \gamma_a \in \Gamma_1 \). For any \( x \in \mathbb{C} \), \( \varphi_{fn}(\gamma_a^{-1} x \gamma_a) = \varphi_{fn}(u^{-1} x u') = \tilde{\omega}_X(u) \varphi_{fn}(u^{-1} x u') \).

Now set \( x = f_\ell (\alpha') \). If \( \varphi(x) \neq 0 \), we must have

\[
x_q = \left( \begin{array}{c} b & -a \\ c & -b \end{array} \right)
\]

with \( v_q(a) = -1 \), \( v_q(b) \geq 0 \) and \( v_q(c) \geq 2 \). However, \( q \mid \xi \), hence \( v_q(b) \geq 1 \) as well. Let \( a = a'/q \). Since

\[
\left( \begin{array}{c} 1 & 1 \\ 0 & 1 \end{array} \right)^{-1} \left( \begin{array}{c} b & -a \\ c & -b \end{array} \right) \left( \begin{array}{c} 1 & 1 \\ 0 & 1 \end{array} \right) = \left( \begin{array}{c} b - j \xi / q \\ c \end{array} \right)
\]

we have \( \varphi_{fn}(u^{-1} x u') = \varphi_{fn}(x) \) for \( u' = x^{-1} \). Thus \( \varphi_{fn}(u^{-1} x u') = \varphi_{fn}(x) \tilde{\omega}_X(u')^{-1} \) for all \( u' \in \mathbb{C}_1^\times \) and

\[
S' = \sum_{u \in \mathbb{C}_1^\times / \mathbb{C}_q^\times} \varphi_{fn}(\gamma_a^{-1} x \gamma_a) L_{\eta \gamma_a^{-1} j \gamma_a}(g_X)
\]

\[
= \varphi_{fn}(x) \sum_{u \in \mathbb{C}_1^\times / \mathbb{C}_q^\times} \tilde{\omega}_X(u')^{-1} \tilde{\omega}_X(u) L_{\eta \gamma_a^{-1} j \gamma_a}(g_X)
\]

\[
= \varphi_{fn}(x) L_{\eta j \gamma_a}(F)
\]

where \( F(\cdot) = \sum_{u \in \mathbb{C}_1^\times / \mathbb{C}_q^\times} g_X(u') \tilde{\omega}_X(u') \). Since \( g_X \) is a newform, and \( F(u) = \tilde{\omega}_X(u) F(\cdot) \) for all \( u \in \mathbb{C}_1^\times \), we must have that \( F = 0 \), whence \( S' = 0 \) and \( S = 0 \) as required.

If \( q \nmid N' \), let \( j(\alpha') = a + bu \in \mathbb{C}_q \otimes \mathbb{Z}_q \). Then \( N(a) = qN(b) = Nm(a + bu) = -v_q \Rightarrow v_q(N(a) - qN(b)) = 1 \Rightarrow v_q(a) \neq 0 \Rightarrow \varphi_q(j(\alpha')) = 0 \), hence \( S = 0 \) in this case as well.

It follows from the proposition above that \( h \) is a scalar multiple of the form \( h_{f, \chi} \) defined in [7] Prop. 2.3. We shall show below that it is in fact a nonzero scalar multiple of \( h_{f, \chi} \) by computing the absolute value of the \( \xi \)th Fourier coefficient for \( \xi_0 \) a fundamental discriminant. We assume henceforth that \( \xi_0 \) is a fundamental quadratic discriminant.

Let \( E_{\mathbb{Q}}(f', c, \xi) \) denote the set of optimal embeddings of \( \mathbb{C}_c \xi_0 \) into \( \mathbb{C}_q' \) modulo the conjugation action of \( \mathbb{C}_q' \). Also let \( E_q \) be the subset of \( \bigcup_{\ell \in \mathbb{E}_{\mathbb{Q}}(f', c, \xi)} \) consisting of classes \( [\ell] \) such that \( \varphi_q(j(\ell(\sqrt{\xi}))) \neq 0 \) and set \( e_q = |E_q| \). Let us recall the following result of Hijikata, which we quote verbatim but specialized to our situation. In the statement below, \( \tau = Z_q \) is the maximal order in \( \mathbb{Q}_q \) and \( \pi = q^{1/2} \) a uniformizer in \( \tau \).

**Theorem 2.3** ([4] Thm. 2.3). Suppose \( B_q \) is split at \( q \) and \( \mathbb{C}_q' = \left( \frac{\tau}{q^{v_\tau} \tau} \right) \). Let \( F_q \) be a quadratic extension of \( \mathbb{Q}_q \); either split or not, \( g \) an integral element of \( F_q \) with \( F_q = \mathbb{Q}_q + \mathbb{Q}_q g \) and set \( \Lambda = \tau + sg \). Let \( f(X) = X^2 - sX + n \in \tau[X] \) be the minimal polynomial of \( g \) over \( \mathbb{Q}_q \). Put \( \bar{R} = \{ \kappa \in \tau \mid f(\kappa) \equiv 0 \mod q^{v} \} \). Let \( R \) be a complete set of representatives for \( \bar{R} \) modulo \( q^v \) and put \( \bar{R}' = \{ \kappa \in R \mid f(\kappa) \equiv 0 \mod q^{v+1} \} \). Define \( \phi_q : F_q \rightarrow B_q \) by \( \phi_q(g) = \left( \frac{x}{-f_\ell} \frac{1}{s-x} \right) \) for \( x \in R \) and \( \phi_q' : F_q \rightarrow B_q \) by \( \phi_q'(g) = \left( \frac{s-x}{q^{v+1}} \frac{-q^{v} f_\ell(x)}{x} \right) \) for \( x \in R' \).
If \( s^2 - 4n \) is a unit of \( \tau \) or \( v = 0 \) (resp. not a unit of \( \tau \) and \( v > 0 \)), the set \( \{ \phi_x \mid x \in R \} \) (resp. \( \{ \phi_x \mid x \in R \} \cup \{ \phi'_x \mid x \in R' \} \)) is a complete set of representatives for the set of optimal embeddings of \( \Lambda \) in \( \mathcal{O}'_q \) modulo the conjugation action of \( \mathcal{O}_q^\times \).

We now use the theorem stated above (with \( \Lambda = \mathcal{O}_{c, \xi, q} \)) to study the sets \( E_q \) in each of the cases that occurs in the definition of \( \varphi \).

Case (a): \( v = 0, (d) = 1 \). We must have \( (c) = 1 \). Setting \( g = \sqrt[\xi]{\tau} \), we may take \( E = \{ j \} \), where \( j(g) = \left( \begin{smallmatrix} 0 & 1 \\ \xi & 0 \end{smallmatrix} \right) \) and \( \varphi_q(j) = 1 \).

Case (b): \( v = 0 \). If \( q \nmid \xi, (d) = 1 \) and \( (c) = 1 \). Setting \( g = \sqrt[\xi]{\tau} \), we may take \( E = \{ j \} \), where \( j(g) = \left( \begin{smallmatrix} 0 & 1 \\ \xi & 0 \end{smallmatrix} \right) \) and \( \varphi_q(j) = 1 \). If \( q \nmid \xi, (d) = 2 \) and necessarily \( (c) = (q) \). Setting \( g = q \sqrt[\xi]{\tau} \), we may take \( E = \{ j \} \), where \( j(g) = \left( \begin{smallmatrix} 0 & 1 \\ \xi & 0 \end{smallmatrix} \right) \) satisfies \( \varphi_q(j) = 1 \).

Case (c1): \( v = 1, (d) = 1 \). Necessarily, \( (c) = 1 \). Take \( g = \sqrt[\xi]{\tau} \) so that \( s = 0, n = -\xi' \). \( \tilde{R} = [\kappa \in \tau, \kappa^2 - \xi' = 0 \pmod{q}] \). If \( q \nmid \xi, R = \{ 0 \}, R' = \emptyset, j_o(g) = \left( \begin{smallmatrix} 0 & 1 \\ \xi' & 0 \end{smallmatrix} \right) \), \( \varphi_q(j_o(g)) = 1 \).

If \( q \nmid \xi, R = 0 \) if \( F_q \) is inert, while if \( F_q \) is split, \( R = \{ x_1, x_2 \}, \mathcal{X}_1, \mathcal{X}_2 \) being the two distinct roots of \( \xi' \). For \( x = q \in R, j_x(g) = \left( \begin{smallmatrix} x & 1 \\ \xi x' & 0 \end{smallmatrix} \right) \).

We only need to consider the case \( q \nmid \xi \). If further \( F_q \) is split, \( \varphi_q(j_x(\sqrt[\xi]{\tau})) = 0 \) unless \( x \in \{ qx_1, qx_2 \} \) in which case \( \varphi_q(j_x(\sqrt[\xi]{\tau})) = 1 \). Also, \( \varphi_q(j(\sqrt[\xi]{\tau})) = 0 \) for all \( j \in R' \). If on the other hand, \( F_q \) is inert, \( \varphi_q(j_x(\sqrt[\xi]{\tau})) = 0 \), and \( R' = \emptyset \).

Case (c2): \( v = 2, (d) = 1 \). Necessarily, \( (c) = q \). Let \( g = q \sqrt[\xi]{\tau} \) so that \( s = 0, n = -q^2 \xi' \). \( \tilde{R} = [\kappa \in \tau, \kappa^2 - q^2 \xi' = 0 \pmod{q^2}] \). \( R = qZ_q, q^2Z_q \). For \( x = q \in R, j_x(g) = \left( \begin{smallmatrix} x & 1 \\ q^2 \xi x' & 0 \end{smallmatrix} \right) \).

Next suppose \( \chi_{0,q} \) is ramified. Again \( (c) = 1 \). Now it is clear that \( E_q \) is nonempty exactly when \( F_q \) is inert at \( q \); in this case, \( E_q \) consists of two elements \( j_1, j_2 \) with \( \varphi_q(j_1(\sqrt[\xi]{\tau})) = 1 \).

Next suppose \( \chi_{0,q} \) is ramified. Again \( (c) = 1 \); \( E_q \) is nonempty exactly when \( q \nmid \xi \) and \( (\xi_0, q) = -w_q \). In that case, \( F_q \) is ramified and \( E_q \) consists of a single element \( j \) with \( \varphi_q(j) \) a complex number of absolute value 1.
On the Fourier coefficients of modular forms of half-integral weight

Case (e): \( q = 2, v = 0 \) and \( R = \{0\} \). If \( \xi_0 \equiv 1 \pmod{4} \), then \( \xi' \equiv 1 \pmod{4} \) as well and \( (d) = (1) \). Pick \( g = c \frac{1+i\sqrt{-d}}{2} \), so that \( s = c \) and \( n = c^2 (1 - \xi')/4 \). Then \( j_0(\sqrt{\xi'}) = \left( \frac{-1}{k_0 \xi'} \right) \cdot 2c^{-1} \). Thus \( \varphi_2(j_0(d \sqrt{\xi'})) \neq 0 \iff (c) = (1) \) and in that case it equals 1. If \( \xi_0 \equiv 4 \) (resp. 0 mod 8), then \( \xi' \equiv 3 \) (resp. 2) mod 8, \( (d) = (2) \) and we may pick \( g = c \sqrt[4]{d} \). Then \( j_0(d \sqrt{\xi'}) = \left( \frac{0}{\sqrt[4]{d}} \right) \). Again, \( \varphi_2(j_0(d \sqrt{\xi'})) \neq 0 \iff (c) = (1) \) and is equal to 1 in this case.

Note that the only primes \( q \) for which \( E_q \) has cardinality greater than 1 are primes of the form \((c1)\) or \((c2)\) with \( F_q \) split or those of the form \((d1)\) with \( F_q \) inert; in each of these cases \( |E_q| = 2 \). The following lemma shows that it is sufficient to consider any fixed embedding \( j \) such that \( j_q \in E_q \).

**Lemma 2.4.** Let \( j = j_e \) and \( j' = j_e' \) be two embeddings satisfying \( j_q, j_q' \in E_q \) for all \( q \). Then \( j \) and \( j' \) have the same conductor and

\[
\varphi_{fin}(j(\epsilon'))L_{\eta_j}(g_\chi) = \varphi_{fin}(j'(\epsilon'))L_{\eta_{j'}}(g_\chi).
\]

**Proof.** It is enough to consider the case where \([j_q] \neq [j_q']\) for exactly one \( q \). Without loss we may also assume that the LHS in the relation above is not zero. As noted above, \( q \) must be a prime of the form \((c1)\) or \((c2)\) with \( F_q \) split or of the form \((d1)\) with \( F_q \) inert. Let us pick an element \( g_q \in B_q^0 \) such that \( j_q = g_q^{-1} \cdot j_q \cdot g_q \) and denote by \( \delta \) the element of \( B_q^0 \) whose component at \( q \) is \( g_q \) and all whose other components are 1. Then \([j'] = [j]^\delta \). Suppose \( \delta = \gamma \cdot u \) with \( \gamma \in B^x \) and \( u \in U' \), so that without loss we may assume \( j' = \gamma^{-1}j \gamma \).

Now

\[
\varphi_{fin}(j'(\epsilon')) = \varphi_{fin}(\gamma^{-1}j(\epsilon') \gamma) = \varphi_{fin}(u \delta^{-1} j(\epsilon) \delta u^{-1}) = (\tilde{\omega}_\chi \cdot ((\chi_\nu \chi) \circ \text{Nm})^{-1}(u) \cdot \varphi_{fin}(\delta^{-1} j(\epsilon) \delta) = \tilde{\omega}_\chi(u) \cdot (\chi_\nu \chi)^{-1}(\text{Nm} \delta) \cdot \frac{\varphi_q(g_q^{-1} j_q(\epsilon) g_q)}{\varphi_q(j_q(\epsilon))} \cdot \varphi_{fin}(j(\epsilon)).
\]

Also letting \( \gamma'_\infty = \gamma^{-1} \gamma_\infty \) and considering \( F^x \) as a subgroup of \( B^x \) via \( j \),

\[
L_{\eta_{j'}}(g_\chi) = \int_{F^x Q^x \setminus F^x} s_{g_q}(j'(x) \gamma'_\infty) \eta(x)d^x x = \int_{F^x Q^x \setminus F^x} s_{g_q}(\gamma^{-1} x \gamma'_\infty) \eta(x)d^x x = \int_{F^x Q^x \setminus F^x} s_{g_q}(x \delta u^{-1} \gamma_\infty) \eta(x)d^x x = \tilde{\omega}_\chi(u)^{-1} \int_{F^x Q^x \setminus F^x} s_{g_q}(x g_q \gamma_\infty) \eta(x)d^x x.
\]

Thus

\[
\frac{\varphi_{fin}(j'(\epsilon'))L_{\eta_{j'}}(g_\chi)}{\varphi_{fin}(j(\epsilon'))L_{\eta_j}(g_\chi)} = (\chi_\nu \chi)^{-1}(\text{Nm} \delta) \cdot \frac{\varphi_q(g_q^{-1} j_q(\epsilon) g_q)}{\varphi_q(j_q(\epsilon))} \cdot \frac{\int_{F^x Q^x \setminus F^x} s_{g_q}(x g_q \gamma_\infty) \eta(x)d^x x}{\int_{F^x Q^x \setminus F^x} s_{g_q}(x \gamma_\infty) \eta(x)d^x x}.
\]
Let $\lambda$ be such that
\[
\lambda_{\varphi_{\text{fin}}(j \in (\alpha'))} L_{\eta_{j'}, (g_X)(\chi)} = \varphi_{\text{fin}}(j \in (\alpha')) L_{\eta_{j'}, (g_X)}.
\]

We now consider separately the following cases:

Case (c1): We can take $j_q(\alpha') = \left( \begin{smallmatrix} i & 1 \\ 0 & i \end{smallmatrix} \right)$ and $j_q'(\alpha') = \left( \begin{smallmatrix} -i & 0 \\ 0 & i \end{smallmatrix} \right)$ where $i^2 = \xi'$, then $j_q$ and $j_q'$ are conjugate by $g_q = \left( \begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix} \right)$. Also $s_{\chi}(x g q) = w_q \chi_q(q) s_{\chi}(x)$, $\varphi_q(g_q^{-1} j_q(\alpha')(g_q q)) = \varphi_q(j_q(\alpha'))$ and $\chi_{\nu}(\text{Nm} \delta) = \chi_{\nu}(q) \chi_{\nu}(q)$. Thus $\lambda = w_q \chi_{\nu}(q) = 1$ by (1.1).

Case (d1): We can take $g_q = u$ where $u$ is as in [7] Sec. 3.2. Then $\varphi_q(g_q^{-1} j_q(\alpha)(g_q)) = \chi_q(-1) \varphi_q(j_q(\alpha))$ and $s_{\chi}(x g_q) = w_q' \chi_q(q) u(0) s_{\chi}(x)$, so that $\lambda = \chi_0(\nu_{\nu}(q) w_q') = 1$, again by (1.1).

Case (c2): We may assume that $j_q(\alpha') = \left( \begin{smallmatrix} i & 1/q \\ 0 & i \end{smallmatrix} \right)$ and $j_q'(\alpha') = \left( \begin{smallmatrix} -i & 1/q \\ 0 & i \end{smallmatrix} \right)$ where $i^2 = \xi'$. Let $x = j_q(\alpha')$. Now we see from (2.5) that for $u' \in \mathfrak{u}_{k} := \left( \begin{smallmatrix} 1 & k/q \\ 0 & 1 \end{smallmatrix} \right) \in \mathfrak{g}_q / \mathfrak{g}_q^{\prime}$, $j_q'$ is conjugate to $j_q$ by $U'$ exactly when $2ik + 1 \neq 0 \pmod q$. Let $\beta_{r}$ be the idèle whose $q$ component is $\left( \begin{smallmatrix} 1 & q/r \\ 0 & 1 \end{smallmatrix} \right)$ and all whose other components are 1. Note that $\beta_{1/2i} = \left( \begin{smallmatrix} 0 & q/1 \\ 1 & 0 \end{smallmatrix} \right)$. Let $j_0 = \gamma^{-1} j \in \mathfrak{g}$ where $\beta_{1/2i} = \gamma u$ for $\gamma \in \mathfrak{g}_x$ and some $u$ in a deep enough subgroup of $U'$. Then
\[
(q-1)\varphi_{\text{fin}}(j(\alpha')) L_{\eta_{j'}, (g_X)} = \sum_{a' = \left( \begin{smallmatrix} k/q & 1 \\ 2ik + 1 \end{smallmatrix} \right) \equiv \left( \begin{smallmatrix} 1 & 1 \end{smallmatrix} \right)}^{q-1} \varphi_{\text{fin}}(j(\alpha')) L_{\eta_{j'}, (g_X)}.
\]

where $\gamma_{\alpha}^{-1} j_0(\alpha') \gamma_{\alpha}' = \left( \begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix} \right)$. Let $\delta_{q}$ (resp. $\delta'_{q}$) $\in \mathfrak{g}_{q}$ be the element whose component at $q$ is $\left( \begin{smallmatrix} 1/q & 0 \\ 0 & 1 \end{smallmatrix} \right)$ (resp. $\left( \begin{smallmatrix} 0 & 1 \\ 0 & q/1 \end{smallmatrix} \right)$) and all whose other components are 1. Since $s_{\chi}(\cdot) = G(\chi, \psi)^{-1} \sum_{k=1}^{q-1} \chi_q(k) s_{\chi}(\cdot \beta_k)$, where $s_{\chi}$ is a new form in $s_{\chi} \otimes \chi_q^{-1}$, we have
On the Fourier coefficients of modular forms of half-integral weight

\[ G(\chi, \psi) \sum_{k' = 1}^{q-1} \chi_{q}^{-1}(k') s_{\chi}(\cdot \beta k') = \sum_{k' = 1}^{q-1} \sum_{l = 0}^{q-1} \chi_{q}^{-1}(k') \chi_{q}(l) s_{\chi}(\cdot \beta k' + l) \]

\[ = \chi_{q}(-1)\chi_{q}(\text{Nm}(\cdot)) \left\{ (qs_{\chi}(\cdot)) - \sum_{j = 0}^{q-1} s_{\chi}(\cdot \beta j) \right\} \]

\[ = \chi_{q}(-1)\chi_{q}(\text{Nm}(\cdot)) \left\{ (qs_{\chi}(\cdot)) + ws_{\chi}(\cdot \delta q) \right\}. \]

Thus, \( G(\chi, \psi)(q - 1) \varphi_{\text{fin}}(j(\alpha'))L_{\eta,j}(g_{\chi}) \)

\[ = \chi_{q}^{-1}(-2\nu q) \int_{F \times Q_{\mathfrak{A}}^1(\mathfrak{A})} \chi_{\psi}(\text{Nm}(x)) \left\{ qs_{\chi}(j(\alpha)\gamma_{\infty}) + w_{q}s_{\chi}(j(\alpha)\delta_{q}\gamma_{\infty}) \right\} dx \]

\[ = \chi_{q}^{-1}(-2\nu q)(q + w_{q}s_{\chi}(q)) \int_{F \times Q_{\mathfrak{A}}^1(\mathfrak{A})} \chi_{\psi}(\text{Nm}(x))s_{\chi}(j(\alpha)\gamma_{\infty}) dx. \]

Since \( \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, s_{\chi}(\cdot \delta' q) = w_{q}s_{\chi}(\cdot) \) and \( \chi_{q}(-1)w_{q} = 1, \) we see that

\[ \varphi_{\text{fin}}(j(\alpha'))L_{\eta,j}(g_{\chi}) = \chi_{q}(-1)w_{q}\chi_{\psi}(q)\varphi_{\text{fin}}(j(\alpha'))L_{\eta,j}(g_{\chi}) = \varphi_{\text{fin}}(j(\alpha'))L_{\eta,j}(g_{\chi}). \]

Thus, in any case, \( \lambda = 1 \) as required. □

The lemma shows that \( |S| = |2\alpha'k\text{vol}(U_{F,c}^{-1}) \cdot 2|L_{\eta,j}(g_{\chi})| \) for any choice of \( j \) such that \( j_{q} \in E_{q} \) for all \( q \), where \( t \) is the number of primes for which \(|E_{q}| = 2 \). This yields the following preliminary proposition.

**Proposition 2.5.** Suppose \( \xi_{0} \) is a fundamental quadratic discriminant satisfying conditions (a), (b), (c) of Prop. 2.2. Then

\[ |a_{q}(x)|^{2} = 4^{k+1}C^{2}|\nu_{q}a_{q}|^{k-1}\text{vol}(U_{F,c})^{-2}|L_{\eta,j}(g_{\chi})|^{2} \]

for any choice of embedding \( j \) such that \( j_{q} \in E_{q} \) for all \( q \) and for \( q \) equal to the conductor of \( j \). Here \( C = \prod_{q \in \eta_{N}}^{\eta_{N}+1} \prod_{q \in \eta_{N}^{-1}}^{\text{vol}(U_{F,c})^{-2}} |L_{\eta,j}(g_{\chi})|\)

The problem is then reduced to computing the quantity \(|L_{\eta,j}(g_{\chi})|^{2}\) to which we apply the method of Waldspurger as outlined in the next section.

3 The method of Waldspurger

3.1 Quadratic forms: the dual pair (GL₂, GO(B))

Let \( \pi \) be the automorphic representation of GL₂(\mathbb{A}) associated to \( f \), \( \pi_{\chi} \) the representation associated to \( f_{\chi} \) and \( \pi' = JL(\pi), \pi_{\chi} = JL(\pi_{\chi}) \) the corresponding representations of \( B^{\times} \). Let \( \psi \) be the usual additive character on \( \mathbb{Q} \setminus \mathbb{A}_{\mathbb{Q}} \) and \( \Theta'(\pi_{\chi}) := \hat{\theta}'(\pi_{\chi}, \psi) \) the theta lift of \( \pi_{\chi} \) to GO(B). Denote by \( \hat{\theta}(\pi_{\chi}) \) the pull back of \( \Theta'(\pi_{\chi}) \) via the natural map \( B^{\times}(\mathbb{A}) \times B^{\times}(\mathbb{A}) \rightarrow \text{GO(B)} \), \((a, b) \mapsto (x \mapsto axb^{-1}) \). It is a theorem of Shimizu that \( \hat{\theta}(\pi_{\chi}) \simeq \pi'_{\chi} \otimes \pi'_{\chi} \). One may also pick an explicit Schwartz function \( \varsigma \in \mathcal{S}(B(\mathbb{A})) \) such that \( \hat{\theta}'(\varsigma, f_{\chi}) \) is a scalar
Let us choose a formula for the torus integral as a product of local zeta integrals (as opposed to Watson’ s choice of places where a multiple of 166 for

By a similar argument as in [15], one sees that with this choice of Schwartz function as in [15]. Finally, if \( \chi_q \) is ramified, we make the following choice for \( \varsigma_q \).

**Definition 3.1.** If \( B \) is split at \( q \), and \( \chi^2 \) is ramified at \( q \),

\[
\varsigma_q \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \chi_q^{-2}(d)I_{Z_q}(a)I_{Z_q}(b)I_{q^2 Z_q}(c)I_{q^2 Z_q}(d).
\]

If \( B \) is split at \( q \), and \( \chi^2 \) is unramified at \( q \),

\[
\varsigma_q \begin{pmatrix} a & b \\ c & d \end{pmatrix} = I_{Z_q}(a)I_{Z_q}(b)I_{q^2 Z_q}(c)I_{Z_q}(d).
\]

If \( B \) is ramified at \( q \),

\[
\varsigma_q(a) = \chi_q^{-1}(Nm(u))I_{C_q}(a).
\]

By a similar argument as in [15], one sees that with this choice of \( \varsigma \) (with \( \langle, \rangle \) being the usual Petersson inner product).

**Proposition 3.2.**

\[
\bar{\vartheta}(\varsigma, f_x) = C' \cdot \frac{\langle f_X, f_x \rangle}{\langle g_X, g_X \rangle} (g_X \times \overline{g_X})
\]

for \( C' = \prod_{q < \infty} \text{vol}(U_{0,q}(\chi)) \).

### 3.2 A formula for the torus integral as a product of local zeta integrals

Let us choose \( \tau \) such that \( B = F + F' \cdot \tau \in \mathbb{N}_{B^+}(F^+) \setminus F^+ \), \( \tau \chi = \epsilon^t \tau \) for \( \chi \in j(F) \). Set \( V_1 = F, V_2 = V_1^+ = F \tau \) and suppose that \( \bar{\varsigma}_q = \sum_{i \in I_q} \varsigma_{1,i} \otimes \varsigma_{2,i} \in \mathcal{H}(V_{1,q}) \otimes \mathcal{H}(V_{2,q}) \). By an application of see-saw duality (and accounting for the measure normalizations),

\[
\frac{\langle f_X, f_x \rangle}{\langle g_X, g_X \rangle} L_{\eta}(g_X) L_{\bar{\eta}}(\overline{g_X}) = \frac{\langle f_X, f_x \rangle}{\langle g_X, g_X \rangle} (g_X \times \overline{g_X})_{F^+(A) \times F^+(A), \bar{\eta} \times \eta}) = \frac{1}{C} (\bar{\vartheta}(\varsigma, f_X))_{(A^0(V_1), A^0(V_2), 1 \times \bar{\eta})} = \frac{1}{C} (\bar{\vartheta}(\varsigma, f_X))_{(A^0(V_1), A^0(V_2), 1 \times \bar{\eta})} = \frac{\sqrt{d} F L(1, \epsilon F)}{2C} \sum_{(\eta_q) \in \prod_{q} L_q} \int_{GL_2(\mathbb{Q}) \times GL_2(\mathbb{A})} f_X(\sigma) \theta_{\varsigma_{1,q}}(\eta)(\sigma) \theta_{\varsigma_{2,q}}(1) d^\times \sigma
\]
On the Fourier coefficients of modular forms of half-integral weight

where the measure in the last expression is the Tamagawa measure. Note that we have used above that \( \eta \) factors through the norm. Now using the fact that the theta lift of the trivial character is an Eisenstein series by the Siegel-Weil formula, and unfolding this Eisenstein series, one sees that the sum in the last expression above equals the value at \( s = 1/2 \) of the analytic continuation of

\[
(2)^{-1} \prod_q \sum_{a \in \mathbb{Z}} \int_{K_0} W_{f_q}(d(a)k)W_{\eta,q}(s_2,\eta)d(a)k|a|^{-1}d^\times \mathbf{a}dk
\]

where \( \Phi_q(s_1, \eta) = |a(\eta)|^{-1/2}r_\psi(\eta, h_0)s_1(0) \) and

\[
W_{\eta,q}(s_2, \eta) = |\text{Nm}(\tau)|^{1/2} \int_{\mathbb{R}^2} r_\psi \left( \begin{pmatrix} \text{Nm}(\tau)^{-1} & 0 \\ 0 & 1 \end{pmatrix} \sigma, h_0 \right) s_2(\tau) \eta(h_0)d^\times h
\]

for any \( h_0 \) with \( \text{Nm}(h_0) = |\text{Nm}(\tau)|^{-1} \det \sigma \) (and is 0 if \( \text{Nm}(\tau)^{-1} \det \sigma \notin \text{Nm}(F^\times_q) \)). Here the measure \( d^\times h \) is chosen such that \( \text{vol}(\mathbb{Z}_q^\times) = 1 \) and \( dk \) such that \( \text{vol}(\text{GL}_2(\mathbb{Z}_q)) = 1 \) and \( \text{vol}(\text{SO}_2(\mathbb{R})) = 1 \). The measure \( d^\times h \) on \( F_q^{(1)} \) is chosen such that \( \text{vol}(F_q^{(1)} \cap \mathbb{O}_F) = 1 \) for \( q \) finite and unramified, \( \text{vol}(F_q^{(1)} \cap \mathbb{O}_F) = 2 \) for \( q \) finite and ramified and such that for \( q = \infty \) it coincides with the measure \( dx/x \) on \( K_\infty^\times \cong \mathbb{R}^\times \).

### 3.2.1 Local setup

To proceed further, it will be useful to set up some purely local notation. Fix a prime \( q \) and in what follows below we work entirely locally but without the subscript \( q \). Suppose \( f_\chi \) has conductor \( \gamma \) at \( q \). By Casellman’s theorem \( W_{f_\chi} \) satisfies

\[
W_{f_\chi}(gu) = \tilde{\omega}_{\chi}(u)W_{f_\chi}(g)
\]

for \( u \in \begin{cases} \begin{pmatrix} \alpha & 0 \\ \gamma & \beta \end{pmatrix} \in \text{GL}_2(\mathbb{R}), \gamma \equiv 0 \mod \gamma \end{cases} \). Let \( F \) be a two dimensional algebra over \( \mathbb{Q} \) (so \( F \) is either the split algebra \( \mathbb{Q}_q \times \mathbb{Q}_q \) or a quadratic field extension of \( \mathbb{Q}_q \)) and denote by \( \sigma \) and \( \tau \) the maximal orders in \( F \) and \( \mathbb{Q}_q \) respectively. Fix an element \( \xi \in F \) with \( \text{tr}(\xi) = 0 \), so that \( F = \mathbb{Q}_q + \mathbb{Q}_q \xi \). Also suppose we are given an embedding \( j : F \hookrightarrow B_q \). Let \( \tau \in F^\times, \tau \neq 0 \), where \( F^\times \) is the orthogonal complement to \( F \) in \( B \) for the norm form and the embedding given by \( j \).

Define for \( g \in \text{GL}_2(\mathbb{Q}_q) \) and for \( s_2 \in \mathcal{F}(F^\times) \),

\[
W_q(s_2, j, \tau, g) = |\text{Nm}(\tau)|^{1/2} \int_{F^\times} r_\psi \left( \begin{pmatrix} \text{Nm}(\tau)^{-1} & 0 \\ 0 & 1 \end{pmatrix} g, h_0 \right) s_2(\tau) \eta(h_0)d^\times h
\]

where \( h \in F^\times \) is any element with \( \text{Nm}(h) = \det(g) \). It is easy to check that if \( \tau \) is replaced by \( \beta \tau, \beta \in F^\times \), the integral (3.1) is multiplied by \( \eta(\beta)^{-1} \). Since \( \eta = (\chi^{-1} \chi_\nu) \circ \text{Nm} | F^\times_{\mathbb{Q}_q} \),

\[
W_q(s_2, j, g) := (\chi^{-1} \chi_\nu)(\text{Nm}(\tau)) \cdot W_q(s_2, j, \tau, g)
\]

is independent of the choice of \( \tau \).
Suppose further that we are given a function \( \varsigma \in \mathcal{J}(B) \). Write \( \tilde{\varsigma} = \sum_i \varsigma_{1,i} \otimes \varsigma_{2,i} \) and consider

\[
I(\varsigma, j, \tau) = \sum_i \int_{Q_p^n} W_\varphi(\Phi(\varsigma; j), \tau, d(-a)k) d(\varsigma; j) \Phi(\varsigma; j) |a|^{-\delta} d\varsigma d\tau d\varphi
\]

where \( \epsilon = \left( \begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix} \right) \). Since \( W_\varphi(\varsigma; j, \tau, \varphi) \Phi(\varsigma; j) \) is bilinear in \( (\varsigma_{1,i}, \varsigma_{2,i}) \), the expression on the right in (3.2) is independent of the decomposition \( \varsigma = \sum_i \varsigma_{1,i} \otimes \varsigma_{2,i} \). Clearly \( I(\varsigma, j, \tau, \varphi) = I(\varsigma_{1,i}, \tau, \varphi) \) for \( \tau \in U_f \). If \( j \) and \( \tau \) are fixed we will omit them from the notation.

For \( \alpha, \beta \in \mathfrak{GL}_2(\mathbb{Q}_p) \), set

\[
J(\varsigma_{1,i}, \varsigma_{2,i}, \alpha, \beta) = \int_{Q_p^n} W_\varphi(\Phi(\varsigma_{1,i}) \Phi(\varsigma_{2,i}) \Phi(\varsigma_{1,i}) \Phi(\varsigma_{2,i}), d(-a)\beta) d\varsigma d\tau d\varphi
\]

and if \( \varsigma = \sum_i \varsigma_{1,i} \otimes \varsigma_{2,i} \), then let

\[
J(\varsigma, \alpha, \beta) = \sum_i J(\varsigma_{1,i}, \varsigma_{2,i}, \alpha, \beta).
\]

4 Computing the local zeta integrals

We assume first that \( q \) is odd and split the computations we need into different cases as given by the table below:

<table>
<thead>
<tr>
<th>B</th>
<th>c</th>
<th>( \eta )</th>
<th>F</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>( \text{M}_2(\mathbb{Q}_p) )</td>
<td>1</td>
<td>( \text{unram.} )</td>
<td>1</td>
</tr>
<tr>
<td>IA</td>
<td>( \text{M}_2(\mathbb{Q}_p) )</td>
<td>q</td>
<td>( \text{unram.} )</td>
<td>split 1</td>
</tr>
<tr>
<td>IB</td>
<td>( \text{M}_2(\mathbb{Q}_p) )</td>
<td>q</td>
<td>( \text{unram.} )</td>

<td>ram. 1</td>
</tr>
</tbody>
</table>

In what follows we use the following notation:

\[
\Phi(\varsigma) = \begin{pmatrix} a & 0 \\ 0 & 1 \end{pmatrix}, \quad \Phi(\varsigma) = \begin{pmatrix} 1 & y \\ 0 & 1 \end{pmatrix}, \quad \Phi(\varsigma) = \begin{pmatrix} 1 & 0 \\ 0 & y \end{pmatrix}
\]

\[
\Phi(\varsigma) = \begin{pmatrix} a & 1 \\ -1 & 0 \end{pmatrix}, \quad \Phi(\varsigma) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \Phi(\varsigma) = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}
\]

Note that

\[
(4.1) \quad \Phi(\varsigma) = -w \Phi(\varsigma) w
\]

\[
(4.2) \quad \Phi(\varsigma) \Phi(\varsigma) = \Phi(-a \varsigma) \Phi(\varsigma) w.
\]
On the Fourier coefficients of modular forms of half-integral weight

Recall also that the character \( \eta \) factors as \( \eta = \tilde{\eta} \circ \text{Nm} \) with \( \tilde{\eta} = \chi^{-1} \chi_\nu \), a fact that we will use at times.

**Note.** If \( F \cong \mathbb{Q}_p \times \mathbb{Q}_q \) is split, then \( \eta = (\eta_1, \eta_2) \) where \( \eta_1 = \eta_2 = \tilde{\eta} \). However, for future use, we will often perform the computations below for an arbitrary character \( (\eta_1, \eta_2) \) with \( \eta_1 \neq \eta_2 \). It will be clear that the final formula obtained is valid even if \( \eta_1 = \eta_2 \) as is the case in our situation.

### 4.1 \( q \) odd, \( \varsigma_f = (1) \)

In this case, \( \pi_{f_3} = \pi(\mu_1, \mu_2) \) is an unramified principal series and \( \varsigma \) is invariant by \( r_\psi(k, h) \) for \( k \in K, \text{Nm}(h) = \det(k) \).

#### 4.1.1 Case 0: \( B = M_2(\mathbb{Q}_q) \), \( \eta \) unramified, \( F \) ramified, \( (c) = (1) \)

Let \( g \in F \) be such that \( \text{tr}(g) = 0 \), \( g^2 = \pi \), where \( \pi \) is a uniformizer in \( \mathfrak{m} \). We may take \( j_\psi(g) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \) and \( \tau = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \). Then \( \varsigma = \varsigma_{1, 1} = \sum_{i=0}^{q-1} \mathbb{I}_{i+\frac{1}{2}, \mathbb{Q}} \otimes \mathbb{I}_{i+\frac{1}{2}, \mathbb{Q}} \). Since \( \Phi(\mathbb{I}_{i+\frac{1}{2}, \mathbb{Q}}, \mathbf{d}(a)) = \delta_{0|a|}^{1/2} \), and

\[
W_\mathfrak{m}(\mathbb{I}_{\mathfrak{m} \mathfrak{r}}, \mathbf{d}(-a)) = \mu(F^{(1)})|a|^{1/2} \eta(a) \mathbb{I}_{\text{Nm}(\mathfrak{r})(a)}
\]

we have

\[
I(\varsigma) = J(\varsigma, 1, 1) = (1 - \mu_1(q)\eta(g)q^{-s})^{-1}(1 - \mu_2(q)\eta(g)q^{-s})^{-1}.
\]

#### 4.2 \( q \) odd, \( \varsigma_f = (q) \)

In this case \( q \mid N, \pi_{f_3} = \sigma(\mu_1, \mu_2) \) special, \( \mu \) unramified with \( \varsigma = \mathbb{I}_{\mathfrak{m} \mathfrak{Q}} \otimes \mathbb{Q}_q \). Suppose \( \mu_1 = \| \cdot \|^{1/2}, \mu_2 = \| \cdot \|^{-1/2} \). Then \( \epsilon = (q) \) and

\[
W_\mathfrak{m}(\mathbf{d}(a)) = |a|^{1/2} |a| \mathbb{I}_{\mathbb{Q}_q}(a), \quad W_\mathfrak{m}(\mathbf{d}(a)w) = -|a|^{1/2} |aq| \mathbb{I}_{\mathbb{Q}_q}(aq).
\]

We have \( \varsigma = \hat{\mathcal{O}}_{\mathfrak{m}} \), where \( \hat{\mathcal{O}}_{\mathfrak{m}} = \left[ \begin{array}{cc} \mathfrak{q} & \tau \mathfrak{r} \\ \tau \mathfrak{q} & \tau \end{array} \right] \) if \( B = M_2(\mathbb{Q}_q) \) and \( \hat{\mathcal{O}}_{\mathfrak{m}} = u^{-1} R \) if \( B \) is ramified.

It is easy to see using (4.1) that \( \varsigma \) is invariant by \( r_\psi(k, h) \) for any \( k \in K_{0, q}, h \in F^x \hookrightarrow B^x, \text{Nm}(h) = \det(k) \). Now a set of representatives for \( K_{0, q} \setminus K \) is \( \{1, \mathfrak{m}(z), z = 0, \ldots, q - 1 \} \). Hence using (4.2) we see that

\[
(q + 1)J(\varsigma) = J(\varsigma, 1, 1) + qJ(\varsigma, w, w) = J(\varsigma, 1, 1) + \alpha_q q J(\varsigma, w, 1).
\]

#### 4.2.1 Case IA: \( B = M_2(\mathbb{Q}_q) \), \( \eta \) unramified, \( F \) split, \( d = 1 \)

Let \( g \) be such that \( \text{tr}(g) = 0, g^2 = u \in (\mathfrak{m}^x)^2, \mathfrak{m} = \mathfrak{r} + \mathfrak{v} \mathfrak{g} \). Thus \( s = 0, n = -u, \hat{\mathfrak{r}} = \{ \xi \in \mathfrak{r} \mid \xi^2 - u \equiv 0 \mod \mathfrak{r} \}, \mathfrak{r} = \{ \alpha, -\alpha \} \) where \( \alpha^2 = u \). For \( \xi = \pm \alpha, j_\psi(g) = \left[ \begin{array}{cc} \alpha & 0 \\ 0 & -\alpha \end{array} \right] \). Take \( \tau = \left[ \begin{array}{cc} 1 & 0 \\ -2 & 1 \end{array} \right] \) and let \( \lambda_\xi : \mathbb{Q}_q \times \mathbb{Q}_q \cong F, \lambda_\xi(\xi, -\xi) = g \). Then \( \varsigma = \varsigma_1 \otimes \varsigma_2 \), with
Thus I and ζ with ζ_1 = \mathbb{I}_σ and ζ_2 = \mathbb{I}_λ(\tau \pi τ) \tau. ζ = ζ_1 \otimes ζ_2 for ζ_1 = \mathbb{I}_σ and ζ_2 = \mathbb{I}_λ(\tau \pi τ) \tau and Φ^2(ζ_1, d(a)) = Φ^2(ζ_2, d(a)) = |a|^f. If η ∘ λ_ζ = (η_1, η_2), we have

\[
W_{η}(ζ_2, d(-a)) = |a|^{1/2} \int_{Q_τ} \mathbb{Q}_ζ((τt^{-1} a) )η(aτ^{-1}, t)d^×t
\]

\[
= |a|^{1/2} \mathbb{I}_q Z_α(a)η_1(q) \sum_{i=0}^{η_2(a)-η_1(a)} \frac{η_2(q)}{η_1(q)}
\]

and likewise

\[
W_{η}(ζ_2, d(-a)) = \frac{1}{q} |a|^{1/2} \mathbb{I}_q Z_α(a)η_1(q) \frac{η_2(aq^2) - η_1(aq^2)}{η_2(q) - η_1(q)}.
\]

Thus

\[
J(ζ, 1, 1) = η_1(q)q^{-\frac{1}{2} - \hat{η} - s}(1 - η_1(q)|q|^{1/2 + \hat{η} + s})^{-1}(1 - η_2(q)|q|^{1/2 + \hat{η} + s})^{-1}
\]

\[
J(ζ, w, 1) = -\frac{1}{q}(η_1(q)q^{-\frac{1}{2} + \hat{η} + s})(1 - η_1(q)|q|^{1/2 + \hat{η} + s})^{-1}(1 - η_2(q)|q|^{1/2 + \hat{η} + s})^{-1}
\]

and

\[
I(ζ) = -\frac{η_1(q)q^{-\frac{1}{2} + \hat{η} + s}}{q + 1}(1 - q^{-2s})(1 - η_1(q)|q|^{1/2 + \hat{η} + s})^{-1}(1 - η_2(q)|q|^{1/2 + \hat{η} + s})^{-1}.
\]

### 4.2.2 Case IB: B = M_2(Q_η), η unramified, F is ramified, d = 1

F is a ramified quadratic extension of Q_η. Let g be such that tr(g) = 0, g^2 = π, π a uniformizer in τ, Λ = τ + g. Then s = 0, n = -π, R = {ξ ∈ τ | ξ^2 - π ≡ 0 mod π} = πτ. R = {0}, R' = 0. For ξ = 0 ∈ R, J_0(g) = (0 1 0). Take τ = (0 1 0). Then ζ = ζ_1 \otimes ζ_2, where ζ_1 = \mathbb{I}_σ and ζ_2 = \mathbb{I}_στ. ζ = \mathbb{I}_σ \otimes \mathbb{I}_στ, where ζ_1 = q^{-1/2} \mathbb{I}_π^{-1} σ, \mathbb{I}_π^{-1} σ, where ζ_1 = q^{-1/2} \mathbb{I}_π^{-1} σ. Hence Φ^2(ζ_1, d(a)) = q^{1/2} Φ(ζ_2, d(a)) = |a|^f,

\[
W_{η}(ζ_2, d(-a)) = |a|^{1/2} η(h_0) \int_{F(1)} \mathbb{Q}_ζ(a(hh_0)^{-1})d^×h = \frac{1}{2} a(F(1))|a|^{1/2} \mathbb{I}_q(a)η(h_0)
\]

\[
W_{η}(ζ_2, d(-a)) = \frac{1}{2} q^{1/2} \text{vol}(F(1))|a|^{1/2} \mathbb{I}_q(a)η(h_0)
\]
On the Fourier coefficients of modular forms of half-integral weight

for any \( h_0 \in F \) with \( \text{Nm}(h_0) = a \). Let \( \tilde{\pi} \) be a uniformizer in \( F \). Then

\[
J(\zeta, 1, 1) = \frac{1}{2} \text{vol}(F(1))(1 - \eta(\tilde{\pi}))|q|^{1/2 + \mu + j} - 1
\]

\[
J(\zeta, w, 1) = \frac{1}{2} \text{vol}(F(1)) \eta(\tilde{\pi})^{-1} \frac{|q|^{1/2 - \mu - s}}{q^{1/2 + \mu + j}}
\]

\[
I(\varsigma) = \frac{1}{2} \text{vol}(F(1)) \frac{1}{q + 1} (1 - \eta(\tilde{\pi}))^{-1} |q|^{1/2 - \mu - j} (1 - \eta(\tilde{\pi})) |q|^{1/2 + \mu + j} - 1.
\]

### 4.2.3 Case IIIA:B: \( B = M_2(Q_\mathbb{Q}), d = q \)

Let \( g_0 \in F, \text{tr}(g_0) = 0, g_0^2 = u \in \mathbb{R}, g = \pi g_0 \). \( \Lambda = \tau + \pi g \). Thus \( s = 0, n = -\pi^2 u, \rho = 0 \).

\( \tilde{R} = \{ \xi \in \tau | \xi - \pi^2 u \equiv 0 \mod \pi \}, R = R' = \{ 0 \} \). For \( \xi = 0 \in R \), \( \xi_0(g) = \left( \frac{0}{\pi^2 u} 0 \right) \). Let \( \tau = \left( \begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix} \right) \). Then \( \zeta = \zeta = \sum_{l = 0}^{q - 1} \zeta_{l,1} \otimes \zeta_{l,2} \) where \( \zeta_{l,1} = \Pi_{r = -(\tau + i l)_{\mathbb{R}}}, \zeta_{l,2} = \Pi_{r = (\tau + i l)_{\mathbb{R}}}. \)

Then \( \zeta = \sum_{l = 0}^{q - 1} \zeta_{l,1} \otimes \zeta_{l,2} \) where \( \zeta_{l,1}(x + y g_0) = \frac{1}{q} \varphi(-iyu) \Pi_{x}((x + y g_0)\tau) \), \( \zeta_{l,2}(x + y g_0)\tau) = \frac{1}{q} \varphi(-iyu) \Pi_{y}((x + y g_0)\tau). \) Hence \( \Phi^s(\zeta_{l,1}, d(a)) = \delta_{\eta[a^s]}, \phi^s(\zeta_{l,2}, d(a)) = \frac{1}{q} \eta[a^s]. \)

Now consider first the case IIIA, i.e. \( F \) is inert and \( \eta \) is ramified.

\[
W_{\eta}(\varsigma_{2,0}, d(-a)) = |a|^{1/2} \eta(h_0) \int_{\mathbb{Z}_{\eta}} \varsigma_{2,0}(a(hh_0)^{-1} \tau)d^xh
\]

\[
= \begin{cases} \frac{2}{q + 1} \eta(a), & \text{if } a \in (\mathbb{Z}_q)^2 \\ |a|^{1/2} \eta(a) \mathbb{I}_{\mathbb{Z}_q}(a), & \text{if } v_q(a) = 0, v_q(a) \equiv 0 \mod 2 \end{cases}
\]

and is 0 otherwise. Since \( \sum_{l = 0}^{q - 1} \zeta_{l,1}(x + y g_0)\tau) = \Pi_{x}(x) \Pi_{y}(y) \),

\[
\sum_{l = 0}^{q - 1} W_{\eta}(\varsigma_{2,0}, d(-a)) = |a|^{1/2} \mathbb{I}_{\mathbb{Z}_q}(a) \eta(a)
\]

we have

\[
J(\varsigma, 1, 1) = \int_{\mathbb{Q}_\mathbb{Q}} W_{\eta}(d(a)) W_{\eta}(\varsigma_{2,0}, d(-a)) |a|^s - 1 d^x a = \begin{cases} \frac{1}{q + 1} & \text{if } |\eta|_{\mathbb{Z}_q^2} = 1 \\ 0, & \text{otherwise} \end{cases}
\]

\[
J(\varsigma, w, 1) = \frac{1}{q} \int_{\mathbb{Q}_\mathbb{Q}} W_{\eta}(d(a)) \left( \sum_{l = 0}^{q - 1} W_{\eta}(\varsigma_{2,0}, d(-a)) \right) |a|^s - 1 d^x a
\]

\[
= - \frac{1}{q} \int_{\mathbb{Q}_\mathbb{Q}} |a|^s |a||\Pi_{\mathbb{Z}_q}(a) \cdot |a|^{1/2} \eta(a) \mathbb{I}_{\mathbb{Z}_q}(a)(1 + \epsilon_F(a))|a|^s - 1 d^x a
\]

= 0

where \( \epsilon_F \) is the quadratic character associated to \( F \). Thus \( I(\varsigma, \frac{1}{2}) = \frac{1}{(q + 1)^s} \) if \( |\eta|_{\mathbb{Z}_q^2} = 1 \) and is zero otherwise.
Next consider the case IIIB, i.e. $F$ is split and $\eta = (\eta_1, \eta_2)$ with $\text{cond}(\eta_0) = q$. Then taking $h = (t, t^{-1}), h_0 = (1, a), g_0 = (\xi, -\xi)$,

$$W_\eta(\xi_2, 0, d(-a)) = |a|^{1/2} \int_{Q^+_q} \zeta_2(2((a^{-1}, t)\tau)\eta_1(t)\eta_2(a^{-1})d^*t.$$ 

Now $\zeta_2(2((a^{-1}, t)\tau) \neq 0 \iff a^{-1} + t \in Z_q$ and $a^{-1} - t \in qZ_q \Rightarrow 0 < v_q(t) \leq v_q(a)$. Suppose $v_q(a) = 0$. Then $\zeta_2(2((a^{-1}, t)\tau) = 0$ unless $a \equiv \alpha^2 \mod q$ for some $\alpha \in Z_q^\times$. In that case, $\zeta_2(2((a^{-1}, t)\tau) = 1$ for $t \equiv \pm \alpha \mod q$ and $0$ otherwise. On the other hand, if $v_q(a) > 0$, then $\zeta_2(2((a^{-1}, t)\tau) = 1$ if $0 < v_q(t) < v_q(a)$ and $0$ otherwise. For $a \in Z_q^\times$, define $C(a) = [(\eta_1\eta_2)(a) + (\eta_1\eta_2)(-\alpha)]/(q - 1)$ if $a \equiv \alpha^2 \mod q$ and to be $0$ if $a$ is not a square mod $q$. Then

$$W_\eta(\xi_2, 0, d(-a)) = C(a)I_{Z_q^\times}(a) + I_qZ_q(a)C'(a)$$

where

$$C'(a) = \begin{cases} 0, & \text{if } \eta_1\eta_2^{-1} \text{ is ramified} \cr |a|^{1/2}\eta_2(a) \sum_{j=1}^{v_q(a)-1} (\eta_1\eta_2^{-1})(q^j), & \text{if } \eta_1\eta_2^{-1} \text{ is unramified.} \end{cases}$$

Since $\sum_i \zeta_2, (x + yg_0) = \mathbb{I}_q(x) I(y)$, setting $C''(a) = |a|^{1/2}\eta_2(a) \sum_{j=0}^{v_q(a)} (\eta_1\eta_2^{-1})(q^j)$,

$$\sum_i W_\eta(\zeta_2, d(-a)) = |a|^{1/2} \int_{0 \leq v_q(t) \leq v_q(a)} \eta_1(t)\eta_2(a^{-1})d^*t$$

$$\quad = \begin{cases} 0, & \text{if } \eta_1\eta_2^{-1} \text{ is ramified, and} \cr C''(a), & \text{if } \eta_1\eta_2^{-1} \text{ is unramified.} \end{cases}$$

Since $\eta_2$ is ramified, $\int_{Q^+_q} W_f(\mathcal{d}(a)C(a)|a|^{1-1}d^*a = \int_{Q^+_q} W_f(\mathcal{d}(a)w)C''(a)|a|^{1-1} = 0$. Thus $J(\zeta, w, 1) = 0$ and

$$I(s, s) = \frac{1}{q+1} I(\zeta, 1, 1)$$

$$= \frac{1}{(q+1)(q-1)^2} \sum_{\alpha \in (Z_q/q \mathbb{Z})^*} (\eta_1\eta_2)(\alpha) = \begin{cases} \frac{1}{q-1}, & \text{if } \eta_1\eta_2 \text{ is unramified} \cr 0, & \text{otherwise.} \end{cases}$$

4.2.4 Case IV A,B: $B = B_q, \eta$ unramified, $F$ inert or ramified, $d = 1$

For $q | N^-$, let $L_q$ be the unique unramified extension of $Q_q$ of degree $2$, $\pi$ a uniformizer in $Z_q$ and $B_\pi$ be the quaternion algebra given by

$$B_\pi = L_q + L_q u$$

$$um = m \pi u \text{ for } m \in L$$

$$u^2 = \pi.$$
On the Fourier coefficients of modular forms of half-integral weight

Fix an isomorphism $B \simeq B_{\pi}$. This isomorphism must necessarily identify $C' \otimes \mathbb{Z}_q$ with $R_q + R_q u$, where $R_q$ is the ring of integers of $L_q$. Also fix $\omega \in R_q$ with $\omega^2 = \alpha \in \mathbb{Z}_q^\times$, so that $R_q = \mathbb{Z}_q + \mathbb{Z}_q \omega$ and $R_q^0 = \mathbb{Z}_q \omega$.

If $F$ is inert, $E_q = \{ j_1, j_2 \}$ where $j_1 : F \to L_q$ are the two isomorphisms of $F$ with $L_q$. Let $j = j_1$ or $j_2$ and take $\tau = \psi$. Then $\varsigma = \varsigma_1 \otimes \varsigma_2$, where $\varsigma_1 = \mathbb{I}_{R_q}$ and $\varsigma_2 = \mathbb{I}_{R_q u}$. $\zeta = \zeta_1 \otimes \zeta_2$, where $\zeta_1 = \mathbb{I}_{R_q}$ and $\zeta_2 = \frac{1}{\sqrt{q}} \mathbb{I}_{R_q u}$. Thus $\Phi^\varsigma(\varsigma_1, d(a)) = \Phi^\varsigma(\varsigma_1, d(a)) = |a|^2$. If $h_0 \in F^\times$ is such that $N(h_0) = \pi^{-1} a$,

$$W_q(\varsigma_2, \tau, d(-a)) = |q|^{1/2} \int_{F^1} r_q(d(\pi^{-1} a), hh_0) \varsigma_2(\tau) \eta(hh_0) d^\times h$$

$$= |a|^{1/2} \eta(h_0) \int_{F^1} \varsigma_2(\pi^{-1} a(hh_0)^{-1}) \eta(h_0) d^\times h$$

$$= |a|^{1/2} \eta(h_0) \mathbb{I}_{q Z_q, q}(\varsigma_2) \eta(d(a))$$

$$J(\varsigma, 1, 1) = \frac{|q|^{1/2 + \frac{u}{2}} + \eta(q) - 1}{1 - \eta(q)(\eta(q)|q|^{1/2 + \frac{v}{2}})^2}$$

$$J(\varsigma, w, 1) = \frac{1}{q} \frac{1}{1 - \eta(q)(\eta(q)|q|^{1/2 + \frac{u}{2}})^2}$$

$$I(\varsigma) = \frac{1}{q + 1} \frac{|q|^{1/2 + \frac{u}{2}} + \eta(q) - 1}{1 - \eta(q)(\eta(q)|q|^{1/2 + \frac{v}{2}})^2}.$$
The formula in the general case can easily be deduced from this special case using the main

Then we are in Case II i.e.

We will only consider the case when

Proof of Thm. 1.1.

The final formula

where

\[ I(\zeta) = \frac{(q + \chi_0(-1))^2}{q(q - 1)^2} I'. \]

where

\[ I' = \frac{(\eta_1 \chi(q)q^{-\frac{1}{2} + \delta + \varepsilon})}{q + 1} (1 - q^{-2\varepsilon}) \times (1 - (\eta_1 \chi(q)q^{1/2 + \delta + \varepsilon})^{-1} (1 - (\eta_2 \chi(q)q^{1/2 + \delta + \varepsilon})^{-1}). \]

4.4 \( q = 2 \)

In this case, \( \pi_f = \pi(\mu_1, \mu_2) \) is an unramified principal series representation, \( \zeta \) is right invariant by \( r_q(k, h) \) for \( k \in K, \text{Nm}(h) = \det k \). For simplicity, we will assume that \( \xi_0 \equiv 4 \mod 8 \) and later deduce the main formula in the general case from the knowledge of the formula in this case. Let \( g = \sqrt{\zeta'}, \, j_0(g) = \begin{pmatrix} 0 & 1 \\ \zeta' & 0 \end{pmatrix}, \, \tau = \begin{pmatrix} ^{-1} & 0 \\ 0 & 1 \end{pmatrix} \). Then \( \zeta = \zeta = \sum_{i=0}^{1} \sum_{j=0}^{1} \xi_1^{ij} \otimes \xi_2^{ij} \), where \( \xi_1^{ij} = \begin{pmatrix} \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \chi \end{pmatrix}, \, \xi_2^{ij} = \begin{pmatrix} \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \xi \chi_0 \chi \end{pmatrix} \). Now \( \Phi^k(\xi_1, \xi_2, d(a)) = \delta_{\theta_0} |a|^k \), and

\[ W_q(1_{\text{F}^q}, d(-a)) = |a|^{1/2} \eta(a) \text{vol}(F^{(1)}) \iota_{Z_2 \cap \text{Nm}(F^q)}(a) \]

if \( \eta = \eta \circ \text{Nm} \). Thus for \( \pi \) any uniformizer in \( Z_2 \cap \text{Nm}(F^q) \), we have

\[ I(\zeta) = J(\zeta, 1, 1) = \frac{1}{\mu_1(\pi) - \mu_2(\pi)} \sum_{n=0}^{\infty} (\mu_1(\pi^{n+1}) \eta(\pi^n) - \mu_1(\pi^{n+1}) \eta(\pi^n)) |\pi^n|^s \]

\[ = (1 - \mu_1(\pi) \eta(\pi) 2^{-s})^{-1} (1 - \mu_2(\pi) \eta(\pi) 2^{-s})^{-1}. \]

5 The final formula

Proof of Thm. 1.1. We only need to put together our computations. We will assume that \( \xi_0 \)

is not divisible by any primes that divide \( \nu \) but do not divide \( N \) and that \( \xi_0 \equiv 4 \mod 8 \).

The formula in the general case can easily be deduced from this special case using the main result of [3].

Case (a): In this case, it follows from the results in [5] that \( I(\zeta) = L_q(1_{\tau}, \pi \otimes \chi_0) L_q(1_{\tau}, \pi \otimes \chi_0) L_q(1, \varepsilon_0) L_q(1, \varepsilon_0) \). Set \( C_q = 1 \).

Case (b): We have assumed \( \xi \) is prime to \( \nu \), hence we are in Case 0. Since \( \mu_1(q) \eta(q) = \mu_1(q) \cdot \chi^{-1} \chi_0(\nu \xi_0) = (\mu_1 \chi^{-1})(q) \cdot \chi_0(q) \), we have \( I(\zeta) = L_q(s, \pi \otimes \chi_0) L_q(s, \pi \otimes \chi_0) L_q(1, \varepsilon_0) \). Set \( C_q = 1 \).
On the Fourier coefficients of modular forms of half-integral weight

Case (c1): If \( q \nmid \xi \), \( F \) must be split and we are in Case IA: \( I(\xi, \frac{1}{2}) = \frac{\mu(q)\omega(q)\chi_\xi}{q+1}L_q(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = 4(q + 1)^{-2} \). If \( q \mid \xi \), we are in Case IB: since \( \eta_\xi(\bar{\xi}) = \chi_\xi^{-1}\chi_\nu(-\nu_\xi) = \chi_\xi^{-1}\chi_\nu(q, |q|^2) = -\chi_\nu(q)w_q \) and \( \chi_\nu(q)w_q = w_q \), \( I(\xi, \frac{1}{2}) = \frac{\nu_\xi(\bar{\pi})L_q(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = (q + 1)^{-2} \) in this case.

Case (c2): We have \( q \nmid \xi \). Since \((\nu \xi_0, q)_q = (\nu, q)_q(\xi_0, q)_q = (\nu, q)_q(\xi_0, q)_q = 1\), we see that \( F \) must be split at \( q \) and we are in Case II. Then \( I(\xi, \frac{1}{2}) = \frac{q}{(q-1)(q+1)}(1 + \chi_\xi(-1)q^{-1})\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = 4(1 + \chi_\nu(-1)q^{-1})^2/q^2 \) in this case.

Case (c3): If \( q \mid \xi \), \( F \) is ramified and we are in Case IB: we may take \( \bar{\pi} = \sqrt{\nu \xi_0} \). Then \( \eta(\bar{\pi})q^{1/2} = (\nu, \nu \xi_0)_q(-w_q) = -(\nu, \xi_0)_qw_q = -(q, \xi_0)_qw_q = -1 \) since \( \left(\frac{q}{q}ight) \neq -w_q \).

\[ I(\xi, \frac{1}{2}) = \frac{1}{q+1}L_q(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \]. Set \( C_q = (q + 1)^{-2} \).

On the other hand, \( q \mid F, F \) is either split or inert. If \( F \) is split, we are in Case IIIB: since \( \eta_\xi = \chi_\xi^{-1}\chi_\nu \), \( \eta_1\eta_\xi \) is unramified and \( I(\xi, \frac{1}{2}) = \frac{1}{q-1} = \frac{1}{(q+1)(q-1)}L_q(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = (q + 1)^{-2} \) in this case. If \( F \) is inert, we are in case IIIA. Since \( \eta = \chi^{-1}\chi_\nu \), \( I(\xi, \frac{1}{2}) = \frac{1}{(q+1)^2} = \frac{q}{(q+1)^2}L_q(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = (q + 1)^{-2} \).

Case (d1): Suppose that \( \chi \) is unramified at \( q \). If \( q \nmid \xi \), \( F \) must be inert at \( q \) and we are in Case IVA: \( I(\xi, \frac{1}{2}) = \frac{\nu_\xi(\bar{\pi})L_q(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(2s, \varepsilon_F)^{-1} \). Set \( C_q = 4/(q^2 - 1) \). If \( q \mid \xi \), \( F \) is ramified at \( q \) and we are in Case IVB: since \( \eta(\bar{\pi})^{-1}q^{-1} = -(\nu, q)_qw_q \) \( = 1 \), \( I(\xi, \frac{1}{2}) = \frac{1}{(q+1)^2}L_q(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = (q^2 - 1)^{-1} \).

Case (e): In this case, it follows from the computation above that \( I(\xi) = L_q(\frac{1}{2}, \pi \otimes \chi_\nu)\mathcal{L}(\frac{1}{2}, \pi \otimes \chi_\xi)\mathcal{L}(1, \varepsilon_F)^{-1} \). Set \( C_q = 1 \).

Case (f): Set \( C_{\infty} = 2 \cdot I(k)^2 \) (see [5] Prop. 4.2.6 and Sec. 5.3 for this case).

Let us now assume first that \( \chi \) is unramified at \( N^- \). Then we see from the computations above that

\[ |a_\xi(h)|^2 = \frac{C(f, \chi_\nu)|\pi|^{-2\xi}|\nu|^{1/2}L(1/2, \pi \otimes \chi_\nu)\mathcal{L}(1/2, \pi \otimes \chi_\xi) \cdot \frac{\langle g_\chi, g_\chi \rangle}{f_{\chi/\chi^+}}. \]

Suppose now that \( \chi \) is possibly ramified at \( N^- \). Then \( \chi \) decomposes canonically as \( \chi = \chi^+ \chi^- \) where \( \chi^+ \) (resp. \( \chi^- \)) has conductor dividing \( N^+ \) (resp. \( N^- \)). Since \( g_\chi \) is a scalar multiple of \( g_{\chi^+} \cdot \chi^- \circ N^+ \), we have \( g_\chi = \alpha \cdot g_{\chi^+} \cdot \chi^- \circ N^+ \), say. Now, by what we have just seen

\[ |a_\xi(h)|^2 = |a|^2C(f, \chi_\nu)|\pi|^{-2\xi}|\nu|^{1/2}L(1/2, \pi \otimes \chi_\nu)\mathcal{L}(1/2, \pi \otimes \chi_\xi) \cdot \frac{\langle g_{\chi^+}, g_{\chi^+} \rangle}{f_{\chi/\chi^+}}. \]
So we only need to relate \( \left\langle g_{\chi}, g_{\chi} + g_{\chi}^+ \right\rangle \) to \( \left\langle f_{\chi}, f_{\chi} + f_{\chi}^+ \right\rangle \). Clearly, \( |\alpha|^2 \left\langle g_{\chi}^+, g_{\chi}^+ \right\rangle = \left\langle g_{\chi}, g_{\chi} \right\rangle \). Also by a familiar computation

\[
\left\langle f_{\chi}^+, f_{\chi}^+ \right\rangle = \prod_{q \nmid \chi} L_q(1, Ad^0(f)) = \prod_{q \nmid \chi} \frac{1}{1 - \frac{q}{\theta}} = \prod_{q \nmid \chi} \frac{q}{q - 1}.
\]

Now we define \( C_q \) for the remaining cases that we did not consider previously.

Case (d1) with \( \chi_q \) ramified: In this case, \( q \nmid \xi \) and \( F \) is inert. Thus set \( C_q = \frac{4q}{(q-1)^2(q+1)} \).

Case (d2): In this case, \( \chi_q \) is ramified, \( q \nmid \xi \), \( F \) is ramified at \( q \). Set \( C_q = \frac{q}{(q-1)^2(q+1)} \).

Finally, if \( \xi_0 \not\equiv 0 \mod 4 \) or \( \xi_0 \), we still define \( C_q \) for \( q \) in cases (b) and (e) to be 1. The formula of Thm. 1.1 follows now from the computations above, those in [5], Thm. 10.1 of [3], Prop. 2.4 and the discussion in Sec. 3.2.
On the Fourier coefficients of modular forms of half-integral weight
